EBOOK PROCEEDINGS

OF

THE ESERA 2011 CONFERENCE:

Science learning and Citizenship

General Editors: Catherine Bruguière, Andrée Tiberghien, Pierre Clément

Co-editors: Virginie Albe, Silvia Caravita, Graça Carvalho, Costas Constantinou, Digna Couso, Jens Dolin, Reiners Duit, Bob Evans, Jane Johnston, Jari Lavonen, Conxita Marquez, Patricia Marzin, Laurence Maurines, Marisa Michelini, Robin Millar, Kai Niebert, Miriam Ossevoort, Roser Pinto, Dimitris Psillos, Miia Rannikmâe, Andreas Redfors, Helene Sorensen, Rosa Maria Sperandeo, Jouni Viiri, Manuela Welzel-Breuer, Abert Zeyer

ISBN: 978-9963-700-44-8

UMR 5191 - CNRS / Université Lyon 2
Interactions, Corpus, Apprentissages, Représentations

EA 4148, Université Lyon 1 - ENSL, Université de Lyon

This ebook contains fourteen parts according to the strands of the ESERA 2011 conference. Each part is co-edited by one or two persons, most of them were strand chairs. All papers in this ebook correspond to accepted communications during the ESERA conference that were reviewed by two referees. Moreover the co- editors carried out a global reviewing of the papers.

ESERA or the editors and co-editors do not necessarily endorse or share the ideas and views presented or implied included in this book. Moreover, the respect of the guidelines concerning the layout of each chapter is under the responsibility of the authors.

The goal of this electronic book is to publish an improved version of the proposal taking into account the discussion during the presentation.

The three formats of presentations during the conference are published in this ebook. The length for the single oral presentation and posters is between 4 and 7 pages. For the symposium there are two possibilities: The whole symposium is presented as a single paper of 15 pages or each contribution can be considered as a single oral presentation (4-7 pages).

This e-book should be referenced as follows:

Bruguière, C., Tiberghien, A., & Clément, P. (Eds.). (2012). *E-Book Proceedings of the ESERA 2011 Conference: Science learning and Citizenship*. Lyon, France: European Science Education Research Association.
ISBN: 978-9963-700-44-8

Individual articles in the e-book should be referenced as follows:

[Author(s)]. (2012). [Title of article], In C. Bruguière, A. Tiberghien & P. Clément (Eds.), *E-Book Proceedings of the ESERA 2011 Conference: Science learning and Citizenship*. Part [strand number] (co-ed. Editors of the strand chapter), (pp.[page numbers]) Lyon, France: European Science Education Research Association.
ISBN: 978-9963-700-44-8

TABLE OF CONTENTS OF THE EBOOK

PART 1: LEARNING SCIENCE CONCEPTUAL UNDERSTANDING

Co-editors: Roser Pinto and Kai Niebert

Theories, models, and empirical results on conceptual understanding, conceptual change and development of competences; methodology for investigating students' processes of concept formation and concept use; strategies to promote conceptual development.

This part corresponds to strand 1. It contains 16 papers.

TABLE OF CONTENTS OF PART 1
LEARNING SCIENCE CONCEPTUAL UNDERSTANDING

CHALLENGING PRE-GALILEAN MISCONCEPTIONS THROUGH ALTERNATIVE VISUALIZATIONS

Estelle Blanquet[1,2] *and Eric Picholle*[3]

Abstract: While duly Copernican, a significant part of primary school teachers-in-training fail to see the point of the (Galilean) principle of relativity. Two inquiry based teaching sequences involving the notion of reference frame were designed to challenge the students' robust pre-Galilean misconceptions, without mathematical requirements. The first sequence makes use of an artist view ("Framed Earth", by Manchu, 1989) and literary representations of the Earth as seen from a lunar point of view. The second one deals with the succession of seasons through analogical models of the Earth/Sun system. Both sequences were tested among future primary school teachers. Half the cohort was only exposed to the latter sequence while the other half experimented both. Artist representations appear to be an effective way to challenge misconceptions where direct experimentation is not available, such as in astronomy problems.

Keywords: Frame of reference; Misconceptions; Principle of relativity; Artist view; Science fiction

INTRODUCTION

While scientifically closed for four centuries, the issue of heliocentrism still puzzles many a layman, to the point that it is now a common cliffhanger for journalistic discussions of scientific literacy. Many studies have established that a small but significant part of the population (typ. 20% — Gallup, 1999) still remain pre-Copernican, and bringing someone to admit that he believes in the Sun revolving around Earth has become a recurrent joke in mass media.

Pre-Galilean conceptions — namely, the existence of a privileged referential, whether heliocentric or geocentric — are even more widely shared. Saltiel (1980) has shown that for most students, "*proper motion and immobility are defined intrinsically, and not with respects to specified bodies and frames.* (…) *Motion and rest are thus fundamentally inequivalent, a typical pre-Galilean view*". Galilean relativity is classically taught through the mathematical exercise of changing the reference frame. Typically, one can then compare the apparent motion of Mars as seen either from the Earth or from the Sun. Students at ease with mathematical tools (namely spatial geometry) or with good spatial visualization skills (Kozhevnokov & al., 2007) thus integrate painlessly the Galilean paradigm, while otherwise bright students, typically of literary background but with a weakness in maths, often fail to even acknowledge the problem, ancient and conceptually simple as it may be.

This pedagogical difficulty is almost as old as Copernicanism itself. One strategy calls on one's "suspension of disbelief", through thought experiments and, more generally, fiction

(Picholle, 2006). It was first developed by Johannes Kepler to overcome the Ptolemaic prejudice. Kepler was probably first both to publish a formal mathematical analysis of the apparent motion of Mars (in *Mysterium Cosmographicum*, 1596) and, considering its public reception (or lack thereof), to try and bypass formalism through a *literary* thought experiment, the *Somnium* (*The Dream, or Lunar Astronomy,* written ca. 1609). Nowadays, while geocentrism is no longer a sensitive issue, estrangement (Parrinder, 2000) and extraction could still ease off the acceptation of an arbitrary point of view.

In the spirit of Kepler's strategy, the aim of the present study is to investigate the impact of contemporary fiction and artist views to help future teachers to overcome their own prejudices.

PRE-GALILEAN TEACHERS?

Many primary school teachers feel uncomfortable with the idea that, from a terrestrial point of view, the Sun rotates around the Earth. To quantify the prevalence of the Relativistic (*i.e.* Galilean) conception of the Solar system, we submitted 99 graduate students to a questionnaire: *"Two persons are discussing. One claims that the Earth rotates around the Sun and the other the opposite. They ask for your opinion. What do you answer? How do you know?"*

Fourteen different majors were represented, including twelve "experts" in physics (M1 of Master in Physics Teaching). All of them had theoretically been taught on the relativity of motion at least at secondary school level. If the Ptolemaic view is absent, the Copernican view is widely shared (> 90%) but seldom justified by scientific arguments: '*I learned it in school'* (26) / *'Because all planets turn around the Sun'* (18). On the other hand, the minority Galilean view (7/99) was always properly justified: '*Both can be said, it depends of the point of view*'. While physics "expert" students tended to favour the phrase "reference frame" over "point of view", only 1 out of 12 used it properly.

GRASPING RELATIVITY: GEOMETRY ISN'T ENOUGH

Two families of obstacles to the understanding of the Galilean paradigm by the students can be identified. One is technical (namely, mathematical), and associated to the capacity to juggle between points of view (Saltiel, 1980). But there is also a Bachelardian epistemological obstacle: *the reluctance to admit that all reference frames can be equally legitimate* (associated or not to a "natural locus"-like Aristotelian prejudice), even when one can juggle between different points of view.

Our hypothesis is than the latter (epistemological) obstacle is involved in the rarity of the Galilean view. Specific work on the physicality of alternate points of view is thus necessary to overcome it.

METHODOLOGY

The training of future primary school teachers normally includes a inquiry-based learning sequence on Astronomy, involving a discussion of the relative position of Earth and Sun through the traditional problem of the succession of seasons on Earth.

We followed the example of Kepler's *Somnium,* in which a narrator describes his trip on the Moon. Looking through his eyes, the reader is then brought to accept the Lunar point of view as physically legitimate. We designed inquiry sequences implementing this idea through contemporary science fiction works, both literary excerpts and artist views.

In combination with a sequence on the spatial relationships involved in Earth seasons, emphasizing their geometrical reciprocity, they allow to tackle both obstacle families.

"Framed Earth" sequence

The "Framed Earth" sequence (Blanquet, 2011) first involves a painting from French artist Manchu (1989), reproduced in Fig. 1.

Manchu's realistic art suggests a stationary Earth in Moon's sky and raises questions: *Does the Earth stay in the frame? Can Moon's inhabitants observe all the parts of the Earth? Do they see Earth' phases? Where are they on the Moon?* Using their previous knowledge about the Moon, students can conclude with adequate questioning and reformulations from the facilitator. During the process, corporal motions and direct visualizations of analogical models facilitate the representation of several Lunar points of view, thereafter readily accepted as legitimate.

Fig. 1: "La Frontière éclatée"

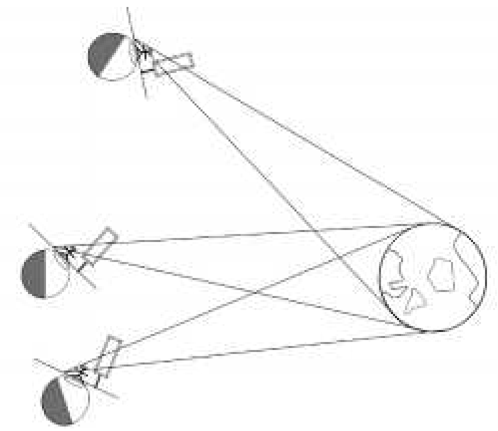

Fig.2: Schematic explanation of the Earth remaining in the Frame

Additionally, excerpts from short stories allow independent tests of students' views through distinct thought experiments: they have to identify hints of Earth's appearance and behaviour and to check them against what they had discovered during the course. They were also brought to discover how Earth's terminator could be used as a clock from the Moon.

A typical excerpt reads:

> 'Like all the best hotels, the Zurich is in Pressure One on the west side so that it can have a view of Earth. I helped Miss Brentwood register with the roboclerk and found her room; it had its own port. She went straight to it, began staring at Earth and going ooh! and ahh! I glanced past her and saw that it was a few minutes past thirteen; sunset sliced straight down the tip of India — early enough to snag another client. "Will that be all, Miss Brentwood?" (…) The view on that side is monotonous except for Earth hanging in the sky.' (Heinlein, 1957)

"Seasons" sequence

Since few primary school teachers-to-be have an advanced scientific background, the usual astronomical sequence also avoids mathematic difficulties by using analogical models (polystyrene balls to represent the planet, etc.) and bodily motions.

Taking into account the phenomena visible from Earth (apparent motion of Sun and stars), the trainees have to propose different models and to discuss their validity, without ever using either the common sense or the authoritative arguments. Alternating points of view, they are brought to acknowledge the geometrical reciprocity of various solar system models and to reconsider their position about the relativity of the motion of Earth and Sun. Previous acceptance of the legitimacy of the Lunar point of view strengthens the physical legitimacy of terrestrial point with regards to the heliocentric one.

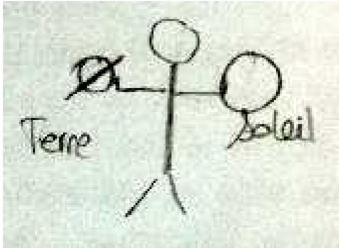

Fig.3: Inclining the Earth' axis to explain alternate seasons in Northern and Southern hemispheres (student drawing)

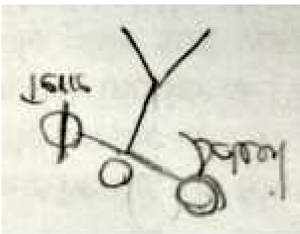

Fig.4: Same as Fig. 3. Inclining the Sun (alternate explanation from the same student)

Assessment methodology

The same questionnaire as above was submitted to a second group of 93 students (M1 Master of « primary school Teaching », none of them Physics majors) after they experienced the "Framed Earth" sequence (with teacher A). They then experienced the "seasons" sequence. Two weeks later, a more detailed questionnaire including slightly different formulations of the same question was asked for comparison (with two different teachers A and B). All sequences were audio- and video-taped for transcription and analysis.

DESTABILISATION OF MISCONCEPTIONS

The “Framed Earth” sequence alone doesn’t appear to significantly affect students’ initial conceptions. In combination, the two sequences appear to yield significant progress towards the Galilean paradigm. No dependence on student’s previous major was observed. Yet, while further studies would be necessary to assess the robustness of this approach, available results suggest that it may be significantly teacher-sensitive method.

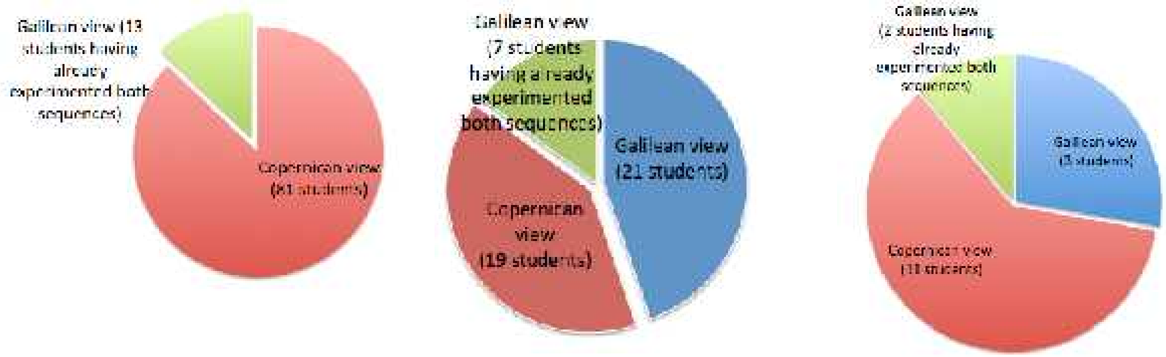

Fig.5 (a): Students’ view after the “Framed Earth” sequence only (93 students) **(b) *idem* after both sequences (Teacher A, 47 students)** **(c) *idem* Students’ view after both sequences (Teacher B, 18 students)**

CONCLUSION

Artist representation appears to affect the expression of paradigmatic misconceptions and to contribute to modify them, at least in this specific case. Considering the robustness of pre-Galilean misconceptions, this is already a significant step. The cognitive processes involved in fiction thus appear as a promising (albeit not autonomous) tool to help overcome epistemological obstacles related to physicality. The ability to imagine oneself in another frame of reference, using artist’s visualization also seems an efficient alternative to introduce the principle of relativity to a public without regard to it mathematical literacy.

CONSTRUCTING SCIENTIFIC KNOWLEDGE IN THE CLASSROOM: A MULTIMODAL PERSPECTIVE ON CONCEPTUAL CHANGE

Carol Callinan[1] *and John Sharp*[1]
[1]Bishop Grosseteste University College Lincoln, Newport Lincoln, UK LN1 3DY

Abstract: Constructivism remains one of the most influential approaches to understanding how children learn in science. Research investigating learning from this approach has led to the development of a wide range of models that aim to explain the underlying processes of how concepts change from alternative explanations of phenomena to those that are scientifically acceptable (Vosniadou, 2008). These models of conceptual change range in their depth and scope with some attributing change to purely cognitive processes (Rumelhart & Norman, 1978) whilst others suggest a role for motivation and affective factors (Pintrich et al, 1993). In addition, contemporary research has begun to explore the links between the role of practical activity, skills development, language, and non-verbal behaviour such as gesture in the development of new concepts and the restructuring of those already held (Crowder & Newman, 1993). This study utilises a cross-sectional design in order to explore the development of science ideas and concepts related to electricity and floating and sinking in children aged 7, 11 and 14 years in English classrooms. The study adopts a new and innovative multimodal approach that combines practical science activities alongside interview and observational protocols together with the addition of gesture analysis. The results from this study form the basis of a critique intended to re-evaluate and inform the debate resulting from different models of conceptual change.

Keywords: Learning in science, constructivism, conceptual change, multimodal research, gesture

INTRODUCTION

Constructivism remains one of the most influential contemporary approaches to understanding how children come to learn science in school classrooms. The constructivist perspective maintains the view that children will have formed some representations of many of the phenomena studied in school science based on their previous experiences and reflection on those experiences in order to understand the world around them (Driver, Asoko, Leach, Mortimer & Scott, 1994). These initial representations are proposed to take the form of 'alternative frameworks' because of the explanatory scope that they provide children with. These 'alternative frameworks' contain conceptual understanding that frequently contrasts with scientific explanations of the same phenomena and therefore they are subject to change when children begin their formal science education (Driver & Easley, 1978; Driver & Bell, 1986). Research investigating learning from this perspective has led to the development of a number of explanatory models identifying underlying mechanisms that support such 'conceptual changes' (for example Vosniadou & Brewer, 1987; diSessa, 1988; Sharp & Kuerbis, 2006, summaries in Vosniadou 2008; Limon & Mason, 2002). These models range in their depth and scope with some placing a high emphasis on purely cognitive processes (Rumelhart & Norman, 1978; Posner, Strike, Hewson & Gertzog, 1982) whilst others attribute a strong role to motivational and affective factors (Pintrich, Marx & Boyle, 1993, Dole & Sinatra, 1998). While the work presented here does not debate the influence that affective factors may have on children's learning it asserts that the current level of diversity between the cognitive models of conceptual change is unhelpful to both teachers and researchers not least of all because it restricts the pragmatic incorporation of key ideas into everyday practices. In addition, however, research associated with each individual model of conceptual change focuses on single areas of scientific phenomena. Vosniadou's weak and radical restructuring for example draws the majority of its evidence from astronomy teaching (Vosniadou & Brewer, 1987). Biology concepts are the focus of Carey's (1985) weak and strong restructuring model. And the development of ideas of force studied in physics is the focus of diSessa's fragmentation theory (1988). Models also frequently lack consistency between the ages of participants recruited, notably diSessa's original contributions from college students whereas Vosnidou's research recruited school age children. One criticism that is more fundamental originates from the lack of consensus regarding the level of mental representation studied. In some cases the aim is to study individual concepts and in others mental models which result from theory structures are utilised. Taken as a whole, this diversity of subjects studied restricts comparison and evaluation of models across scientific domains and prevents the models being evaluated for their utility in informing teaching across scientific curricula. In order to overcome these difficulties the work presented here evaluates the models within comparative contexts in two science domains, notably in the development of children's ideas in electricity and floating and sinking (the Archimedes principle).

Contemporary literature typically approaches the assessment of conceptual knowledge through verbal reports that are accessed through interviews or task-based activities (Osborne & Freyberg, 1985; Primary Space Projects, 1990/1994). Whilst this approach has been successful for generating a wide body of understanding regarding the knowledge that children hold, the bias towards language and linguistic capabilities may prevent a comprehensive understanding of children's knowledge particularly if children are not able to clearly or fully articulate what they know (Goldin-Meadows, 2000). In order to overcome this potential bias, the work presented here investigates the development of scientific ideas and concepts from a multimodal perspective. The multimodal approach to understanding children's learning is a new and innovative research area but one developing rapidly. Initial findings from wider research adopting this approach have demonstrated that during the course of their learning children utilise a number of different expressive modes in order to acquire conceptual knowledge. These modes include verbal dialogue, written pieces, drawings and other expressive art forms and non-verbal communication such as gesture, eye gaze and body posture (Kress et al, 2001). Whilst Kress et al's research focused on how different modes of activity support children's acquisition of concepts in science other researchers (for example Goldin-Meadows, 2000) have investigated the role that non-verbal language such as gesture has in revealing children's existing conceptual knowledge. One early analysis conducted by Crowder and Newman (1993) investigated the gesture and speech of thirteen children who were learning the science concepts associated with seasonal change. The results revealed that some gestures were 'redundant', others served to enhance the ideas expressed through speech, and in some cases gestures served as carriers of scientific meaning that was not present in language.

This led Crowder and Newman to conclude that "*as long as ideas outstrip scientific vocabulary, one can expect to see gestures used by elementary science students to carry unstated ideas"* (p.176). In a summary paper that drew on a body of research investigating different areas of children's problem solving ability Goldin-Meadows et al

(1993) suggest that stability between speech and gesture characterise a stable understanding of a concept, mismatch between the two elements characterises the time in which children are moving between conceptual understandings. It was argued that the "*gesture-speech mismatch signals to the social world that an individual is in a transitional knowledge state"* (Goldin- Meadows et al, 1993, p.279). This was a particularly attractive idea for the work undertaken and presented here as it highlights a window of opportunity through which it may be possible to capture the processes of conceptual change as it actually occurs. It is proposed that this method enables a more comprehensive exploration of how conceptual understanding develops.

The work presented here discusses an initial analysis of findings from an ongoing doctoral level research project currently in the main data collection and early analysis phases.

RATIONALE

This project specifically investigates the following research questions:

- how and to what extent do multimodal analyses of children's verbal and non-verbal communication facilitate understanding of the science ideas and concepts that children have;
- to what extent can such analyses be utilised in order to explore and understand the dynamics that support conceptual change?

METHOD

The research presented here utilised a cross-sectional design by studying the scientific ideas and concepts of three groups of children aged seven, eleven and fourteen years in English Primary and Secondary schools. A total of 101 children took part in the study, the children were distributed as follows across the three age groups; 34 aged seven, 44 aged eleven and 15 aged fourteen. All of the children participating in the study completed two practical science activities, one in electricity and one in floating and sinking. The practical activities were designed to elicit children's ideas by probing understanding as they completed familiar tasks (for example, the construction of simple circuits) whilst subsequent tasks were designed to challenge existing ideas (for example, an analogy of electron movement in a simple circuit using 'smarties'). These activities permitted the analysis of both existing ideas and concepts and the opportunity to observe the outcome when concepts begin to change or are challenged.

The practical science activities took place in small groups (approximately five children of the same age in each group). The activities were highly contextualised to the concepts studied, interactive and dialogic in nature and included protocols from participant observation and interview based methodologies. Each practical science activity lasted approximately one hour. All were audio-video recorded in order to capture events fully and to obtain gesture in transmission.

In order to explore the potential role of each response type the transcription and the subsequent analysis focused on the modes and areas shown in figure 1.

Levels of Comparison
Between Activities
Between Age Groups
Between Participants

Analysis of Written Responses
Analysis of Gesture and Non-verbal Responses
Analysis of Social Interaction
Analysis of the Activity

Figure 1: The different levels of comparison and analysis explored in the study.

Transcripts coded both verbal and non-verbal responses collected throughout each of the activities. Analyses of the data included both within and between age group comparisons for children's ideas and concepts related to each of the science topics. Verbal and non-verbal data were interpreted using a content analysis approach and analysed in order to capture matches and mismatches between the two forms of communication.

RESULTS

Although this project is still in the early stages of analyses the results are beginning to reveal important information about children's gestures. Our data demonstrates that children use five different types of gesture, these gestures contain both scientific and social information (Callinan & Sharp, 2011) figure 2 below provides an overview of the types of gestures.

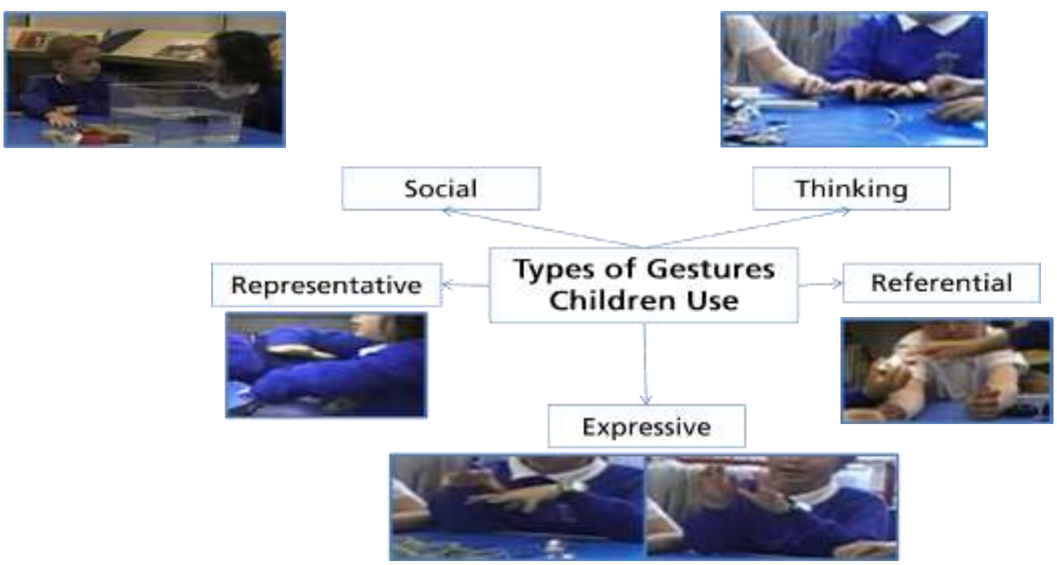

Figure 2: The types of gestures that children use when completing practical science activities and discussing their ideas (Callinan & Sharp, 2011).

Scientific gestures came in four main forms:

- referential – e.g. pointing to objects, pictures or people in the immediate environment;
- representative – e.g. re-enacting the behaviour of objects, pictures, or people;
- expressive – e.g. often including repetitive movements or building on representative gestures revealing the values associated objects, pictures or people;
- thinking – e.g. finger drumming, waving hands, head holding or face and hair stroking.

While scientific gestures appear to play a crucial role in facilitating our understanding of children's scientific ideas, social gestures also have an important role for facilitating our understanding of how young children use input from peers in order to structure their responses to probes of knowledge or seek social support when they are experiencing uncertainty or difficulty in generating a response. During the course of this study there are many instances which demonstrate how children have used such non-verbal approaches to eliciting help from each other. In one example, 'Daniel' (7 years old) used a social gesture whilst discussing his ideas related to floating and sinking. As he spoke Daniel he paused mid- sentence, moved his head to look in turn at each of his neighbours, and after receiving no response from them, he continued to speak. This gesture was interpreted as Daniel's non- verbal way of exploring whether these was agreement for his ideas within the other members of the group. Whilst these gestures can be interpreted as demonstrating little information regarding children's scientific understanding they are particularly helpful for revealing how children negotiate meaning in groups.

Early analyses investigating the possible match – mismatch between verbal and non-verbal communication revealed that for children who produce non-verbal gestures these can contain valuable information regarding their ideas that are not included in the verbal responses. For example, analyses of path tracing during discussions of electricity circuits demonstrated non- verbal clues to children's underlying mental models that may not be reflected in what they say. Our data demonstrates that although children frequently give similar verbal response, for example, 'the electricity flows through the wires to the bulb', the children draw three distinct forms of paths to represent this 'flow' of electricity in the circuit. Some children use one hand to draw a path that begins at the battery and follows the wire before stopping at the bulb. Other children use one hand to draw a path that begins at the battery, follows the path of the wire to the bulb before continuing around the second wire and stopping at the battery. Finally, some children use both hands to draw a path that begins at the battery, each hand then follows a different wire until they meet at the bulb and stop there. This final example is resonant of the 'clashing currents' model discussed in the research literature (Osborne et al, 1991). It is proposed that results such as these support the need for a more detailed analysis of children's gesture and support the view that children's gesture can indeed reveal vital information about children's ideas in science.

The between subjects analyses demonstrated that children's ideas regarding scientific phenomena change over time and become increasingly more scientific. For example, the children aged 7 years initially demonstrated an object-centred understanding of the scientific phenomena associated with floating and sinking. This initial understanding is biased towards the size and weight of the object being explored. The children aged 11 years still possessed object-centred frameworks, however their discussions expanded to include factors of weight, size and properties of materials, thus demonstrating an early understanding of the concept of density. It is only at 14 years that the children began to consider a range of other variables that may have influenced whether objects float or sink, for example the behaviour of the liquid in which the object is placed.

The analyses also revealed that when existing ideas are challenged through practical science activities some children begin to immediately incorporate the new ideas into their existing schema whilst others appear more resistant to the new explanation. Changes in ideas can be observed in the children's verbal responses following participation in the activities, however, in some cases the change in ideas can also be observed in the gestures that children produce. In one example drawn from our floating and sinking activities Sam (11 years old) demonstrates a change in his non-verbal gestures following the challenge of his ideas. At the beginning of the activity Sam's gesture related to his ideas of sinking was as follows, he used his left hand, which was held flat with the palm facing downwards, to make a downward sweeping motion. After Sam's ideas had been challenged through our demonstration of upthrust and water displacement his gesture changed so that his hand was held in a 'c' shape with the palm facing upwards and he used this hand to made a downward movement. This change in gesture appears to illustrate a change in Sam's ideas regarding the forces involved in sinking. His initial gesture appears to indicate that he locates the force which makes the object sink as acting from above. However, after of our discussion of upthrust his gesture is altered so that it reflects the supportive force that is located from beneath the object. His verbal explanation afterwards also contained more complex information and he stated that sinking is "the gravitational pull, pulling something heavy under water". Further analysis of data such as this will be used in order to investigate whether our results can support any of the current models of conceptual change.

CONCLUSIONS

It is proposed that the multimodal, task-based approach presented here offers a more comprehensive route for studying children's existing ideas and concepts of the scientific phenomena associated with electricity, and floating and sinking and probably all phenomena by extension. It is also suggested that verbal analyses of children's responses to probes regarding their ideas used in isolation are insufficient on their own and can lead to biases in results that may fail to account for children's actual knowledge and result in the misclassification of the underlying frameworks that the children hold. The multimodal approach is particularly helpful for understanding younger children's ideas especially when they find it difficult to articulate their ideas and concepts coherently or fully.

In addition, our early analysis suggests that different types of gesture may have different functions and an understanding of these can further our understanding of what children know and can do. It is also suggested that the research presented here highlights the requirement for further similar studies with different groups of participants, for example, further investigation is necessary in order to understand the way in which older participants may use multimodal representations when explaining their science ideas. Such research should ideally explore a range of participants including post G.C.S.E., A level and H.E. students as well as student teachers and lecturers. By exploring the way in which gestures are used to complement and extend verbal explanations of science concepts and ideas it may be possible to better understand how knowledge of science is communicated and it is suggested that this might have implications for assessment, pedagogy, and curriculum development.

STUDENTS' LEARNING PROCESSES IN THE FIELD OF SPECIAL RELATIVITY.

Kyriaki Dimitriadi[1], Krystallia Halkia[1] and Dimitrios Stavrou[2]
[1] *University of Athens, Greece*
[2] *University of Crete, Greece*

Abstract: A major topic that has marked "modern physics" is the Theory of Special Relativity (TSR). The present work focuses on the possibility to teach and learn basic ideas of the TSR in the upper secondary school. Its aim is to investigate students' learning processes towards the two axioms of the theory and their consequences, namely the relativity of simultaneity, time dilation and length contraction. Based on a teaching and learning sequence, developed specifically for this study, five sets of interviews were conducted with forty 10th grade students (aged 15-16). The interviews were oriented to the so-called "teaching-experiment". The results show that upper secondary education students are able to cope with the basic ideas of the TSR. There are some difficulties though, related to the following students' conceptions: a) There is an absolute frame of reference, b) equivalent observers are identical and there is a privileged observer and c) objects have fixed properties. These difficulties seem to be reinforced by the way school science is taught, which provides students with a 'cognitive framework' based on Newtonian mechanics.

Keywords: Special Relativity, Upper Secondary Education, thought experiment, learning processes, teaching experiment.

BACKGROUND, FRAMEWORK AND PURPOSE

The Theory of Special Relativity (TSR) is one of the most significant scientific advances of the 20th century which has changed our understanding of the physical universe. It suggests that the physical world is relativistic, in the sense that measurements of time, space and mass depend on the relative motion of the object and the observer (Shabajee & Postlethwaite, 2000). Space and time cannot be separated from each other; they are part of a single entity, spacetime (Taylor & Wheeler, 1991, p.7). However, it still leaves us with a deterministic view of the physical universe in which variables are related in such a way that a change of one variable produces a definite and predictable change in another dependent variable (Shabajee & Postlethwaite, 2000).

Science Educators recognize the pedagogical value of this topic, since it gives rise to a new form of looking at the extremes of the natural world, namely the extremely fast (Arriassecq & Greca, 2010). Science education research in this field deals with students' understanding of basic ideas of TSR in the university level (e.g. Hewson 1982; Scherr 2001) and in the secondary level (e.g. Borghi et al., 1993; Guisasola et al., 2009).

This research shows that students hold pre-Galilean notions as far as *motion and velocity* are concerned. In particular, motion and velocity are recognized as physical properties of the moving object, independent of observers (Saltiel & Malgrange, 1980). As a result, students do not define the velocity of a body with respect to a frame of reference (O' Brien-Pride, 1997 in Scherr, 2001).

Students tend to consider the *frame of reference* as a “decorative ploy” with no explanatory purpose (Panse, Ramadas & Kumar, 1994). The inertial character of a frame of reference is considered to be a ‘relative’ property, rather than an intrinsic one (Ramadas, Barve & Kumar, 1996) and the term is used as a ‘magic word’ because it does not have any specific interpretative function for them (Pietrocola & Zylbersztajn, 1999).

As far as the *speed of light* is concerned, students do not realize that it is invariant. They admit that the speed of light is constant, but this stems from the idea that speed is absolute generally and it is not specified with respect to a frame of reference (Villani and Pacca, 1987).

In addition, students believe that there are ‘*privileged observers’*, with immediate access to the ‘proper’ values of spatial and temporal parameters which characterize the motion (Hosoume, 1986 in Villani & Pacca, 1987). Thus students violate the *Principle of Relativity,* since they do not consider the observers equivalent.

Furthermore, *time dilation* and *length contraction* are considered as optical illusions (Angotti et al., 1978) or “distortions of perception” (Hewson, 1982). Thus students are reluctant to accept them as real.

Taking these findings into account the present work focuses on the possibility to teach and learn basic ideas of the TSR in the upper secondary school. The aim is to investigate students’ learning processes towards the two axioms of the theory and their consequences, namely the relativity of simultaneity, time dilation and length contraction.

METHODOLOGY

Based on an educational analysis of the science content structure of TSR (Dimitriadi & Halkia, 2010) and a pilot study (Dimitriadi, Halkia & Skordoulis, 2009), a teaching and learning sequence was developed. The empirical investigation was designed as a learning process study. In order to collect the data, interviews and two questionnaires (one before and one after the interviews) were used. The interviews were oriented to the so-called ‘teaching experiment’, which has been applied with success in order to investigate students’ learning processes in new fields (Katu, Lunetta & van de Berg, 1993; Stavrou, Duit & Komorek, 2008). Teaching experiment may be viewed as Piagetian critical interviews deliberately employed as teaching and learning situation. The interviewer assumes both the roles of a ‘classical’ interviewer, who tries to interpret the students’ individual conceptions, and of a teacher, who must have answers to students’ conceptions and make the appropriate intervention at just the right moment (Komorek & Duit 2004).

Forty students of the upper secondary school (grade 10; age 15-16) took part in the investigation. The students were divided in 10 groups (with 4 students each). Five sets of interviews (with a time interval of 1-3 days between them) for each group took place. Every set lasted approximately 60 minutes. The main points of the interviews were:

1st Interview - The first axiom of the TSR (The Principle of Relativity): Students were expected, using everyday examples, to come to the conclusion that there is no way to realize if they are moving with a constant speed or not, so these situations are equivalent.

2nd *Interview - The second axiom of the TSR (The Invariance of the Speed of Light):* Students should conclude that the speed of light is constant and invariable using a thought experiment, where two observers in a train measure the speed of the light when the train is not moving and when its motion is uniform

3rd Interview - The relativity of simultaneity: Students had to handle the relativity of simultaneity using the thought experiment "Einstein's train paradox".

4th Interview - The relativity of time: Students had to come to the conclusion that time is relative using the "light-clock" thought experiment.

5th Interview - The relativity of length: Students should conclude that length is relative as well. The thought experiment used in this case was about two observers who move relative to each other and conduct different length measurements.

The first author carried out the interviews, which were audio taped and transcribed. Due to the explorative character of this study methods of qualitative content analysis were applied (Erickson, 1998).

RESULTS

The main findings of the study show that students are able to recognize the basic ideas of the TSR and to deal with its consequences which have to do with the relativity of time and space.

They face some difficulties though, since they believe that a) there is an absolute frame of reference, b) equivalent observers are identical and there is a privileged observer and c) objects have fixed properties. Students' conceptions and their learning processes are presented analytically in the following:

a) Frame of reference

Trying to define whether they are moving or not, students do not realize that motion is a relative property. Thus, at the beginning, when they try to define if they are moving, they do not use reference points at all.

Student B2: We are moving when we change our position.

When they start using reference points in their answers, they tend to choose objects which are fixed to the ground. They argue that we cannot use as a reference point a moving object:

Student F3: We cannot use the car as a reference point

Student F2: Unless it is in the parking.

Some points of reference are 'more appropriate' according to the students. They imply that actually there is a privileged frame; the ground's frame of reference. Even when they change frame of reference and they use the sun instead of the ground, they keep determining the motion with respect to the sun exclusively. So students believe that motion is not a relative property depending on the chosen frame of reference. Instead they believe that it is absolute.

As a consequence, they argue that velocity is also absolute and it becomes a property of the moving body.

Student J2: Velocity is standard. It is not a force to add or to subtract. It is v, it doesn't change.

To face this idea, in the first session a number of examples were discussed, where students had to deal with several points of reference. It was considered crucial that students should start handling problems with frames of reference beyond the ground's or the sun's frame of reference. So they elaborated problems which took place in a ship, in an airplane, on another planet etc.

An interesting point is that the alternative idea that velocity is absolute seems to lead to the right conclusion as far as the 2nd axiom is concerned. Students argued that light has its “natural” speed, which is constant. At the same time though, they answered that the observers’ measurements could be different.

Student B2: Light has always the same speed. What the observers measure... well, this depends on how fast they are going.

So it was important to deal with the fact that velocity is defined with respect to a frame of reference, in order to realize light’s special properties.

b) Observers

Applying the first axiom, a problem arose from the way students perceive the concept of equivalence. They believe that equivalent observers conduct identical measurements. This causes some difficulties when dealing with the relativistic effects, since students argue that the observers should make the same measurements and the same observations.

Furthermore, dealing with relativistic effects, they implied that there is a privileged observer, usually the one who stands on the ground and in some cases at a specific point

Student B1: I believe that the observer who is not moving is the best. Because in your daily life when you are standing still you have plenty of time to observe something.

Student E4: Does the observer have the right position? Is he in the middle?

In addition, students believe that what differentiates the observers is not only their relative motion, but also that they have different position. This idea came up mostly when they dealt with the relativity of simultaneity; they associate the time of an event with the time at which an observer receives a signal from the event, as also Scherr, Shaffer and Vokos (2002) point out. Although it was made clear to them that we are referring to intelligent observers, who are able to elaborate their observations in order to come to a conclusion, students were not able to realize that the observers’ different position does not differentiate the results.

It seems that students believe that events happen independently of what the observers perceive. There is a ‘privileged’ observer though, the one who stands at the ‘right point’. As a result, this observer perceives the facts as they really happen.

Student E2: In nature, things happen only once. What a person sees or feels is something different.

This idea was confronted by laying emphasis on the Principle of Relativity. The fact that they had to apply the first axiom in order to answer to the question “Who is right” whenever the observers conducted different measurements, helped them to realize that there is no privileged observer since they are equivalent, according to the TSR’s first axiom.

c) Objects Properties

Dealing with the relativity of the length, students have strong objections. It seems more difficult for them to accept this relativistic effect comparing to the relativity of the time, as length is considered as a “property” of the things in itself; thus it cannot change. Time on the other hand is not associated to objects, so it could have a subjective character. At the same time, students show their commitment to a mechanistic view of the world in which objects have fixed properties such as length, mass etc. as Hewson (1982) has pointed out.

Student C3:	It is not possible. 20cm are 20 cm. They are neither 15, nor 35...
Teacher:	Respectively, 5sec are 5sec...
Student C3:	This is different...
Teacher:	Why?
Student C3:	Time is something else... Time is relative

In order to face this difficulty, emphasis was laid on the fact that both the relativity of time and the relativity of length are consequences of the invariance of the speed of light. The thought experiment with the "light clock" helped them to make this connection; using the time measurements, they were able to find the length of an object. So they concluded that if time is relative, length is relative as well.

CONCLUSIONS AND IMPLICATIONS

This study offers an insight into upper secondary students' learning processes about Special Relativity. It shows that students in this level are able to realize the basic ideas of the theory and to deal with its consequences relevant to the relativity of time and space. Specifically, they deal with problems which are in contrast to their everyday experience effectively, and they started questioning about their privileged position in the Universe, which is a very important aspect in their way of thinking

Student:	The observer does not realize the relativistic effects, because he deals with the facts from his point of view. He doesn't know that we have a different opinion... But our opinion is not better than his...

Nevertheless, they restrict TSR's validity in the way the observers perceive the events or conduct measurements. They seem to try to incorporate the Theory of Relativity, to Classical Physics. Their ideas seem to be the "product of Einsteinian branches grafted to Newtonian roots" (Hewson 1982).

The results of the present study lead to the conclusion that students seem to think with absolute terms. What we should consider, is how the teaching of school physics influences their way of thinking; it seems to reinforce these problems. Especially, the way students have been taught classical mechanics; the idea of absolute motion is deeply rooted in their thinking. So it is important in the secondary education to liberate students from the idea of an absolute frame of reference (Villani & Pacca 1987). Moreover, "by providing children with a 'cognitive framework' derived from Newtonian mechanics and presenting this both as unproblematic and all-powerful (when we know that...it is fundamentally incorrect) we are taking steps designed to make any subsequent learning of 20th century relativistic ideas completely difficult" (Shabajee & Postlethwaite, 2000).

REASONING SCHEMATA ACTIVATED BY SECONDARY EDUCATION STUDENTS IN ORDER TO SOLVE CHEMICAL KINETICS QUESTIONS

José Manuel Domínguez Castiñeiras[1] *& José Sánchez Piso*[1]
[1]Department of Experimental Science Teaching. School of Education Sciences. University of Santiago de Compostela. Av. Xoán XXIII, s/n. 15782-Santiago de Compostela. Spain.

e-mail: josemanuel.dominguez@usc.es

Abstract: this research is part of a broader one in which the influence of a teaching proposal about Chemical Kinetics on the learning of 4th grade of Compulsory Secondary Education (15 to 17 years old) students has been studied. In this paper the initial characterization of the sample is described. In order to achieve this, we have designed the reasoning schemata *speed of reaction* activated by the students when answering the proposed questions.

Keywords: Reasoning schemata, Secondary education, Chemical kinetics

BACKGROUND, FRAMEWORK AND PURPOSE

This paper is part of a broader research that studies the impact of a specific teaching proposal about Chemical Kinetics on the learning process. Special attention has been paid to the distinctive functional knowledge of scientific competence (OCDE, 2010).

The contributions of the schemata theory have proven useful to tackle this problem, as they allow to characterize the way in which student discourse is structured from his reasoning and actions. Regarding this, we have considered the definitions of schemata by Rumelhart and Ortony (Rumelhart & Ortony, 1977; Rumelhart & Norman, 1981). From this perspective, reasoning and thinking schemata (Domínguez *et al*., 2003, 2005) are representations of the knowledge acquired and built by students through learning. This knowledge can be activated in order to use or process specific information.

Rationale

To find out which changes take place in student knowledge, it has been considered necessary to initially characterize the sample. This is the goal of the current work and the first hypothesis of the investigation. This way, in the communication of results, the baseline conditions will have already been defined.

To this end, a series of activities have been proposed to the students. The results of this initial set of tests have been examined using: 1) a per item analysis about the justificative reasonings and the action strategies that the students use in their answers and 2) an analysis of the reasoning schemata and action schemata that students activate when explaining, interpreting and predicting the proposed facts, phenomena and situations. Using these schemata the discourse structure of the students have been characterized, from their arguments and actions.

Learn about what students know is not only a requirement of experimental design, but also gives useful information for the design of the teaching proposal, for using this knowledge in the teaching discourse and practicum and the development of proper methodological approaches.

From this point of view, the following research questions have been posed:

How to make explicit the implicit thinking schemata that students have in a certain instant and a certain domain?

How to make the schemata independent of the situation (problem) used to activated them?

Which are the schemata activated before instruction?

To answer these questions, referential knowledge (reasoning and action) schemata have been developed, to allow dimensioning the desirable knowledge from the point of view of school science.

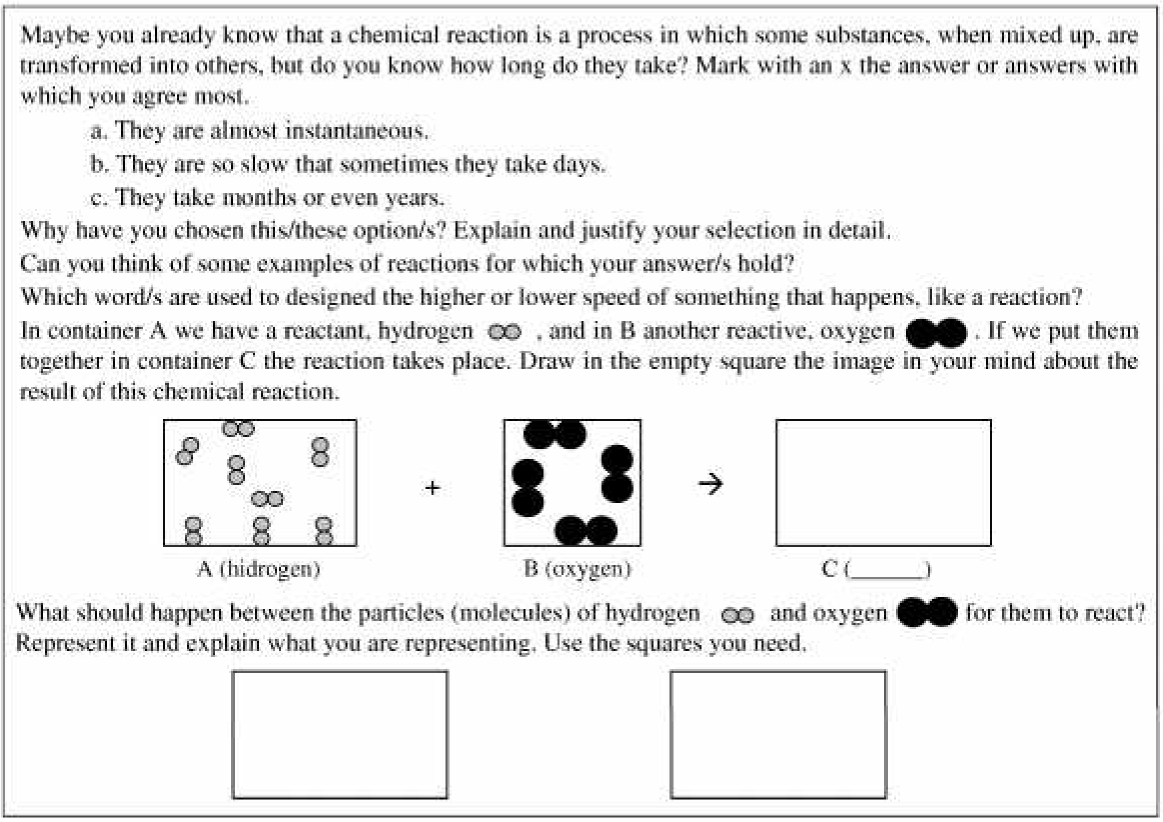
METHODS

Sample

The research is based in a class of fourth year of Compulsory Secondary Education, consisting of a group of five male students and eleven female students aged between fifteen and seventeen. The sample was incidental, where equal representation was not pursued, but a natural and typical situation in education.

Information collection strategy

A total of 8 tests were designed, but because of space reasons only one is shown here (Figure 1).



Maybe you already know that a chemical reaction is a process in which some substances, when mixed up, are transformed into others, but do you know how long do they take? Mark with an x the answer or answers with which you agree most.

a. They are almost instantaneous.
b. They are so slow that sometimes they take days.
c. They take months or even years.

Why have you chosen this/these option/s? Explain and justify your selection in detail.

Can you think of some examples of reactions for which your answer/s hold?

Which word/s are used to designed the higher or lower speed of something that happens, like a reaction?

In container A we have a reactant, hydrogen , and in B another reactive, oxygen . If we put them together in container C the reaction takes place. Draw in the empty square the image in your mind about the result of this chemical reaction.

What should happen between the particles (molecules) of hydrogen and oxygen for them to react? Represent it and explain what you are representing. Use the squares you need.

Figure 1. Initial characterization test

They are practical activities and problematic situations related to the kinetics of reactions. Certain questions are posed that are to be solved with the corresponding jusitificative reasoning. The students' speech and actions have been recorded in audio and video.

Information collection strategy

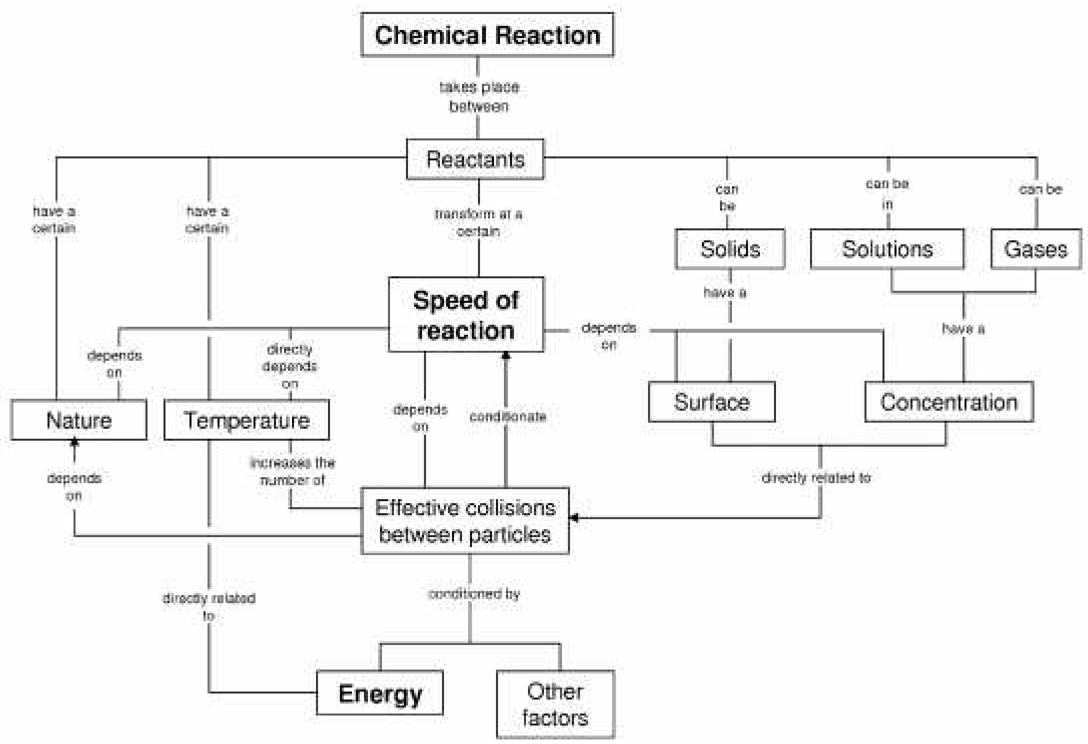
Per-item analysis

A per item analysis has been performed to evaluate the answers of the students to each of the 8 tests. They are exemplified using illustrations and explicative reasonings developed by them. As previously stated, we will only refer to the test described in Figure 1.

Per-scheme Analysis

From the per-item analysis, the explicative discourse developed by the students to interpret chemical reaction kinetics have been fragmented by building their reasoning schemata *"speed of reaction"*.

To avoid researcher bias in the interpretation of the student knowledge (Kesidou & Duit, 1993) the referential scheme desirable from school science has been built (Scheme 1). It will also allow us to graphically represent the reasoning schemata of the subject students.



Scheme 1. School science referential scheme

The structure of relations by which the four factors that modify the speed of reaction (nature of reactants, temperature, surface, concentration) are identified is made explicit in this scheme. Also, the relations between these factors and the interpretative model based in collision theory are also represented in the scheme.

The reasoning scheme is composed of three subschemata: **chemical reaction, speed of reaction** and **energy**, together with a variable, *effective collisions between particles*.

The macroscopic aspects appear on the top of the scheme: *reactants* have certain properties (*nature, temperature, surface* and *concentration*) on which speed of reaction depends.

The explanation of the effect of these factors appears at the bottom of the scheme, depending on the *effective collisions* between particles and the influence of **energy**.

RESULTS

Per-item analysis

In the argumentative discourse built by the students we have found two kinds of reasoning. Note that their answers have been translated from Galician, the official language of Galicia (Spain):

A group (students 3, 5, 7, 8, 13, 15) says that speed of reaction depends on reactants, as stated by student 13:

> *"I think it depends on the substances that you mix. For example, it is not the same to mix water with alcohol (they mix quickly) than to mix water with oil (that do not mix)" (student 13)*

Student 3 uses an everyday life example that makes her doubt of her opinion.

> *"I think they are instantaneous, as I do not think it has to take so long to make a reaction, but if we look at the reaction between oxygen and iron we'll se that they are not so spontaneous" (student 3)*

Wrt. the second group (1, 2, 4, 6, 9, 10, 11, 12, 14, 16), of students who think that reactions are instantaneous, most students identify reactions with mixings. Some solutions are in fact chemical reactions, but not others. Student 16 justifies his answer using his lab experience. Probably this explains the extended opinion in the class of matching reactions with mixings.

> *"... when we do mixings in the lab, reactions take place almost instantly" (student 16)*

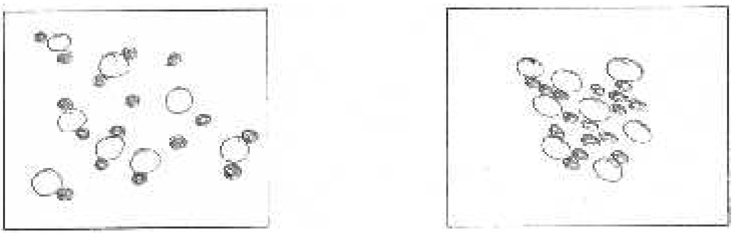
Student 9 is the only one that mentions the term "speed", but she belongs to the group of students that thinks that reactions take place almost instantly. She bases her opinion in combustion examples.

> *"I base in the example of a burning paper. Combustion is instantaneous" (student 9).*

The goal of this work goes beyond this, and we ask ourselves if students will be able to translate this notion to an atomic-molecular explanation. Almost all students make explicit the unions between particles, as can be observed in the following example:

> *"For a reaction between two components to occur, these must mix and touch to achieve the reaction" (alumno 10).*

In the drawing of this student it is observed that, after organizing the atoms in the new molecule, she describes their union when they form the compound.



Student 11 is the only one that searches for a relation between speed of reaction and temperature, saying that it inverse, justifying this by the facility with which particles get together.

> *"There must be a temperature decrease for particles to get near" (student 11).*

This argumentation is probably influenced by precedent instruction, although his prior knowledge is still far from the collisions with which we pretend they justify the influence of the different factors on speed of reaction.

Per-scheme analysis

From the per-item analysis and comparing with the reference scheme (Scheme 1), the relations present in the student discourse through all the 8 tests of the initial characterization have been extracted. This has allowed us to build the reasoning schemata *speed of reaction* of the students, independently of each test, and order them in levels and sublevels.

A total of 5 levels and 8 sublevels *i,o* of the initial characterization of the sample have been established, for the 16 students in the sample under study (Table 1).

These levels indicate the existance of significative differences in the reasoning structures that the students activate. The sublevels indicate the existance of individuals or groups with very similar reasoning schemata.

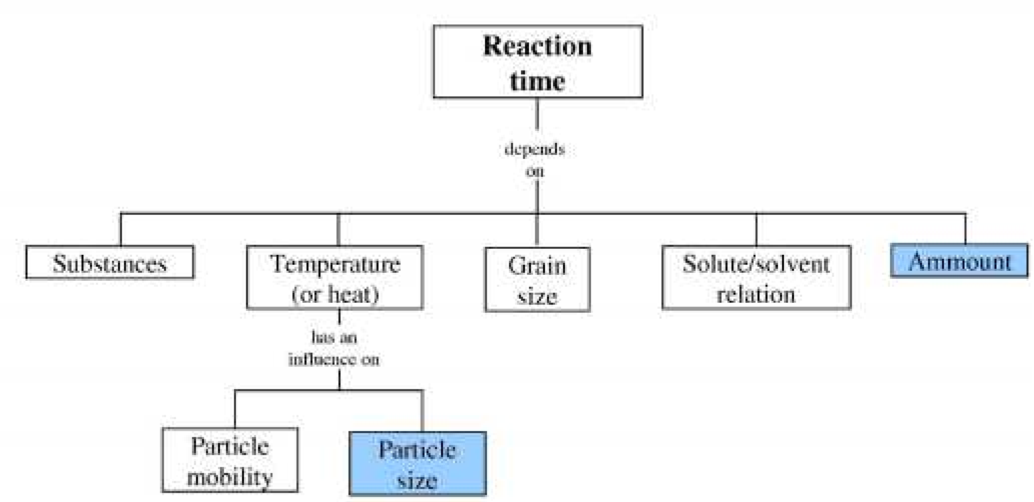
From Table 1, some consequences for the elaboration of the didactic proposal can be inferred: the majority of students do not consider the four factors that modify speed of reaction. Nonetheless, with the help of the test statements, some do feel their influence. Together with these factors, all students propose either others (specially the ammount of reactant or solvent) or they establish an inverse relation between speed of reaction and temperature or concentration.

Levels	*i5*		*i4a*			*i4b*		*i3a*	*i3b*		*i3c*	*i2a*	*i2b*	*i2c*		*i1*
Students	3	5	1	4	11	7	15	8	9	10	14	13	12	6	16	2
Fundamental relations																
Time depends on substances	x	x				x	x	x				x				
Time depends on temperature	x	x	x	x	x	x	x		x	x	x		x			
Time depends on grain size	x	x	x	x	x			x	x	x				x	x	
Time depends on solute/solvent relation	x	x	x	x	x	x	x				x					
Relations far from school science																
Time depends on other factors	x			x		x	x		x	x	x		x			
Time depends on quantity	x	x	x	x	x		x			x				x	x	
Time inversely depends on temperature					x					x						
Time inversely depends on concentration								x	x	x		x			x	x
Temperature influences particle mobility.	x	x								x			x		x	
Temperature influences particle proximity.			x	x	x	x	x	x	x	x	x	x		x		
Time influences particle size.		x														x

Table 1. Reasoning schemata *Speed of reaction*: relations and order levels

None of the students build a discourse that explains, following the atomic-molecular model, the influence of these magnitudes.

From Table 1 and comparing with the reference scheme (Scheme 1) the reasoning schemata of each student can be graphically represented. This allows for an easier comparative analysis between them. Scheme 2, corresponding to student 3 (Table 1-level i5) shows what we intend to say.



Scheme 2. Student 3's reasoning scheme

In this level we include the reasoning scheme that is nearer to the point of view of school science. The dominant scheme ***reaction time***, and variables *substances, temperature, grain size* and *solute/solvent relation* have been activated. It was decided not to call the dominant scheme *speed of reaction* because only student 9 uses this expression before it appears in the test statements of the initial characterization. For the same reason the terms nature, surface and concentration are not used, they have been substituted by substances, grain size and solute/solvent relation. Together with these variables present in the referencial scheme appear other alternative factors relevant for the reaction time (represented with a gray weave).

CONCLUSIONS AND IMPLICATIONS

The current analysis offers valuable information on how to focus teaching.

It can be concluded that students try to use scientific terms which meaning they do not understand, and this leads them to match reaction with mixing, or to apply to atomic-molecular particles terms belonging to the macroscopic world, such as student 9 (already cited) who says that oxygen atoms must fuse with hydrogen atoms. No terms belonging to chemical kinetics appear, nor terms belonging to collision theory.

The answer of student 3 points out the need of explaining the concept of speed of reaction with examples showing that chemical processes take place neither instantaneously nor with the same speed in all cases. It will be necessary to point out that certain reactions, such as the reaction between hydrogen and oxygen (spontaneous from the point of view of thermodynamics) seem not to take place, and explain this from the perspective of Chemical Kinetics.

Students respond to a model different from the collision model. They identify that it is important for particles to get near to react, but not with a collision or interaction. It could be said that the contact between them does not take place at random, because of their agitation, but that instead a static model is used, in which particles do not continuously vibrate, but move in the mixing reactives, and thus they meet.

Student answers include relations that are repeated regularly, so they constitute reasoning schemata. They are incipient schemata, *seeds* in Vygotski's (1979) nomenclature, which teachers must use to work in their ZPD (zone of proximal development) and structure the new knowledge.

The students' reasoning schemata are, in most cases, poorly structured, incomplete and based on undesirable knowledge from the point of view of education science. Because of this, they are not very useful reasoning schemata –*speed of reaction*- to interpret that the speed of reaction of a chemical reaction is influenced by factors as *reactive nature*, *temperature*, *solid surface* and *solution concentration*.

Reasoning schemata can be distinguished wrt. the representative referencial of school science (scheme 1) which makes possible to sort those schemes in different levels and sublevels (table 1), allows to quantify the progress of learning and study the statistical significance of the existing differences.

Abstract: The widespread of antibiotic resistant bacteria raises major public health concerns. Aggravated by the lack of new antibiotics, the increase of antibiotic resistant bacteria hinders our ability to control infectious diseases. Having in mind the reported link between antibiotic misuse and overuse and increased resistance phenotypes, public health education interventions to promote rational antibiotic consumption are fundamental. This study highlights the outcomes of a hands-on project to address antibiotic resistance at high school levels (ages 15 to 17). The project *Microbiology recipes: antibiotics à la carte,* was designed to promote students' understanding of biological concepts and processes underpinning the notion of antibiotic resistance, such as bacteria adaptability and the antibiotics' specificity and modes of action. Combining wet and dry lab activities with group discussions, the project is structured to engage the participants in routine microbiology procedures. The effectiveness of this project was assessed through a pre-/post design approach involving 25 high school students (aged 15 and 16). The results provide qualitative and quantitative evidence of students' increased awareness of the perils of antibiotic resistance and of the importance of responsible behaviours. The implications of these findings for science education are discussed.

Keywords: Antibiotics, hands-on activities, health education, high school.

INTRODUCTION

The widespread of antibiotic resistant bacteria raises major public health concerns. Aggravated by the lack of new antibiotics, the increase of antibiotic resistant bacteria hinders our ability to control infectious diseases. In this context, the public's individual choices concerning antibiotics are of paramount importance, particularly considering the reported link between antibiotic misuse and overuse and increased resistance (van de Sande-Bruinsma et al., 2008). Therefore, it is fundamental to promote prudent antibiotic use. Accordingly, several health education initiatives and resources have been developed, as for instance the ones made available by the Centers for Disease Control and Prevention (http://www.cdc.gov/drugresistance/campaigns.html). Nevertheless, not only has the effectiveness of these programmes and materials been seldom validated, but most importantly, studies have evidenced that the general public continues to engage in misinformed antibiotic consumption (Grigoryan et al., 2007). The problem is particularly pervasive amongst the younger populations (Buke et al., 2005).

Imbued by the need to diversify and consolidate interventions to promote rational antibiotic use, this study focuses on the outcomes of a weeklong hands-on project to address antibiotic biosynthesis and resistance at high school levels (ages 15 to 17 years). The rational for this study was based on the following assumptions: firstly, that understanding the concept of antibiotic resistance is required for judicious antibiotic use; and secondly, that this understanding is not straightforward given the abstractness of the knowledge underlying the notions of bacteria and antibiotics, and preconceived ideas surrounding these concepts (Davey et al., 2002; Milandri, 2004). Building on these elements, the project *Microbiology recipes: antibiotics à la carte*, aims to engage the participants in practical activities designed to boost their interest and enhance their understanding about the concept of bacteria, antibiotics, and antibiotic resistance.

RESEARCH DESIGN AND METHODOLOGY

The project was implemented as part of University of Porto's Junior University (http://universidadejunior.up.pt/index.php/paginas/english/home), a program aimed at promoting S&T (Science & Technology) education amongst elementary and high school students (aged 11 to 17), through the development of research-based Summer projects designed by university lecturers and executed by undergraduate and graduate students. *Microbiology Recipes: antibiotics à la carte* was developed as an extension of Fonseca et al. (2011)'s activity about the antibiotic effects of phytoactive compounds, aiming to assess its educational outcomes in an informal context. This was a one-week long project, integrating wet lab (e.g. microscopy, extraction and testing of plant-derived antimicrobials) and dry lab (e.g. bioinformatics, discussions and analysis of scientific papers) activities that took place every day from 9.00 am to approximately 5.30 pm. The modules covered various scientific notions and concepts including those of: bacteria, such as reproduction and growth; antibiotics, for instance production and alternative drugs; and antibiotic resistance addressing causes, consequences, and dissemination of antibiotic resistance genes. The topics and procedures are aligned aiming to: improve the participants' knowledge and understanding about the contents address; promote positive attitudes and beliefs about antibiotic use; enhance awareness towards potential implications of antibiotic misuse/overuse for public health; and increase interest about this issue.

From June 28 to July 9, 2010, 23 grade 10 (n=19, 12 females) and 11 (n=4, 3 females) science students (aged 15 and 16) participated in this project. Following a pre-/post design, qualitative and quantitative data were collected through direct observations, analysis of participants' reports and questionnaire analyses (open and closed questions, Tables 1 and 2). This study focuses on the outcomes of the questionnaire analyses. Data were recorded, codified and categorized. Content analysis of the open questions in both questionnaires was performed according to the guidelines available in Krippendorff (2004) and Weber (1990). The correct and incorrect notions provided by the participants in each question were quantified, and their pre-/post-test variations measured. Using SPSS v.19.0, descriptive and inferential statistical analyses (one sample t-tests, McNemar test and Wilcoxon signed ranks test) were performed to compare the participants' responses.

RESULTS AND DISCUSSION

Understanding the concepts of bacteria, antibiotics, and antibiotic resistance

Concerning the project's learning outcomes (Table 1) positive impacts on the participants' understanding of the concept of bacteria, antibiotics and antibiotic resistance were identified. The participants developed a more elaborated notion of bacteria, as detailed below. There was an increase in the number of correct notions incorporated in the participants' responses, as well as a decrease in the number of incorrect notions (Table 1). However, these pre-/post-test differences were not statistically significant, which is not surprising given the knowledge expectably developed by these students, who had just finished the 10th and 11th grades. In Portugal, the 10th and 11th grade Biology and Geology programmes comprise contents pertaining, respectively, to *cell structure* and *uni-/multicellularity* (Direcção-Geral de Inovação e de Desenvolvimento Curricular [DGIDC], 2001), and *taxonomy and classification systems* (DGIDC, 2003). Therefore, the participants had already been acquainted with the notion that bacteria are *unicellular* ($n_{\text{pre-test}}$=10 vs. $n_{\text{post-test}}$=15, p=0.23), *prokaryotic* ($n_{\text{pre-test}}$=14 vs. $n_{\text{post-test}}$=17, p=0.73) *microorganisms* ($n_{\text{pre-test}}$=10 vs. $n_{\text{post-test}}$=6, p=0.23). Contrasting with the previously reported tendency for bacteria to be associated with illness (Milandri, 2004), the participants were already aware that bacteria can be both beneficial and harmful for humans (Table 1). However, by the end of the project, the participants were able to provide more correct examples of both types of bacteria (Table 1). For instance, in the post-test there were more participants mentioning the positive roles played by the human microbiota ($n_{\text{pre-test}}$=4 vs. $n_{\text{post-test}}$=13, p=0.01). In addition, whereas in the pre-test most of them referred to disease causing bacteria in general to exemplify the negative impact of these microorganisms (n=11), in the post-test they were able to discriminate different types of potentially pathogenic bacteria (e.g. *Bacillus cereus*, n=6; *Ureaplasma urealyticum*, n=2) and bacterial diseases/illnesses (e.g. foodborne illness, n=3; tuberculosis, n=1).

Having a general idea about the phases of bacteria's growth cycle is useful to understand the importance of using antibiotics as prescribed, especially in what concerns the need to finish the course of the treatment (Davey et al., 2002). Nevertheless, the notion of bacterial growth is not always straightforward, namely because it refers to increases in cell number, instead of cell size, as traditionally envisioned by most people (Srivastava & Srivastava, 2003). In this study, the participants' conceptualization of bacterial growth was significantly improved. While prior to their participation, 15 participants did not convey a single idea about this issue, by the end of the project, 24 were able to provide at least one correct notion in this regard (Table 1). The number of participants reporting notions of *bacterial death* and *growth* increased from three and seven in the pre-test to, respectively, 24 and 22 in the post-test (p<0.01). In fact, whereas in the pre-test none of the participants referred specifically to bacteria's growth rate, in the post-test, 22 emphasized the microorganisms' exponential growth. Furthermore, 16 participants were able to identify the four growth phases comprised in bacteria's growth cycle, while none of them did so in the pre-test (p=0.00).

There were significant increases both in the number of students able to define antibiotics correctly, and in the amount of correct notions included in their answers (Table 1). For instance, the notion that some antibiotics affect growth and others kill bacteria directly was mentioned by 16 of the participants in the post-test, and five actually referred to antibiotic's modes of action. This knowledge is essential to increase awareness about the specificity and effects of antibiotics, and enable individuals to make informed decisions on antibiotic use. The results further indicate a tendency for a more comprehensive appraisal of the steps involved in antibiotic drug development and production (Table 1). Whereas there were six participants that mentioned drug development stages in the pre-test, in the post-test 15 indicated tasks involved in antibiotic production, including microbiological ($n_{\text{pre-test}}$=5 vs. $n_{\text{post-}}$

$_{\text{test}}=8$, $p=0.25$) and animal testing ($n_{\text{pre-test}}=1$ vs. $n_{\text{post-test}}=6$, $p=0.01$), isolation and extraction of the compound ($n_{\text{pre-test}}=2$ vs $n_{\text{post-test}}=10$, $p=0.02$) and antibiotic formulation, namely making it more stable by adding other substances ($n_{\text{pre-test}}=1$ vs. $n_{\text{post-test}}=9$, $p=0.01$). The acknowledgement of the complexity and time involved in antibiotic drug development, contributes to a deeper appreciation of the constraints posed at counteracting resistance (Alfonso, 2005).

Table 1. Project's learning outcomes, based on the pre-/post-survey analysis.

	Pre-test	**Post-test**	**Statistics**
How do you define bacteria?			
Number of students providing at least one correct notion	$n=22$	$n=25$	$\chi^2(1)=1.33$, $p=0.25$
Mean number of correct notions (e.g. "unicellular prokaryotic organism")	$M=1.96 \pm 1.27$	$M=2.56 \pm 1.26$	$Z=-0.98$, $p=0.33$
Mean number of incorrect notions (e.g. "unicellular prokaryotic organism")	$M=0.20 \pm 0.50$	$M=0.08 \pm 0.28$	$Z=-0.82$, $p=0.41$
Are bacteria beneficial or harmful for humans? Give some illustrative examples.			
Number of students answering that all bacteria are harmful	$n=3$	$n=0$	$\chi^2(1)=1.33$, $p=0.25$
Number of students answering bacteria can be both beneficial and harmful	$n=22$	$n=25$	$\chi^2(1)=1.33$, $p=0.25$
Mean number of correct examples of beneficial bacteria (e.g. "bacteria in yogurts")	$M=0.56 \pm 0.58$	$M=0.96 \pm 1.17$	$Z=-1.70$, $p=0.09$
Mean number of correct examples of harmful bacteria (e.g. "disease causing bacteria")	$M=0.52 \pm 0.51$	$M=1.24 \pm 1.27$	$Z=-2.49$, $p=0.01$
Describe the main phases in bacteria's life cycle.			
Number of students providing at least one correct notion	$n=10$	$n=24$	$\chi^2(1)=12.07$, $p=0.00$
Mean number of correct notions (e.g. "bacteria reproduce asexually")	$M=0.52 \pm 0.71$	$M=3.36 \pm 1.00$	$Z=-4.26$, $p=0.00$
Number of students answering "I do not know" or no response	$n=15$	$n=1$	$\chi^2(1)=12.07$, $p=0.00$
How do you define antibiotic?			
Number of students providing at least one correct notion	$n=7$	$n=20$	$\chi^2(1)=9.60$, $p=0.00$
Mean number of correct notions (e.g. "medicine that kills bacteria")	$M=0.40 \pm 0.71$	$M=2.44 \pm 2.36$	$Z=-3.59$, $p=0.00$
Mean number of incorrect notions (e.g. "medicine that stimulates the production of white blood cells")	$M=0.36 \pm 0.49$	$M=0.00$	$Z=-3.00$, $p=0.00$
Number of students answering "I do not know" or no response	$n=2$	$n=0$	$\chi^2(1)=0.50$, $p=0.50$
Describe how an antibiotic is produced.			
Number of students mentioning at least one correct notion/phase	$n=6$	$n=15$	$\chi^2(1)=7.11$, $p=0.00$
Mean number of correct notions (e.g. "… isolate the compound", "… test the compound on animals")	$M=0.40 \pm 0.91$	$M=2.04 \pm 2.13$	$Z=-2.60$, $p=0.01$
Number of students answering "I do not know" or no response	$n=17$	$n=7$	$\chi^2(1)=8.10$, $p=0.00$
How do you define antibiotic resistance?			
Number of students providing at least one correct notion	$n=11$	$n=21$	$\chi^2(1)=5.79$, $p=0.01$
Mean number of correct notions (e.g. "… the bacteria do not die in the presence of the antibiotic")	$M=0.52 \pm 0.65$	$M=1.24 \pm 0.88$	$Z=-2.60$, $p=0.01$
Mean number of confused notions (e.g. "the bacteria continue to be pathogenic")	$M=0.28 \pm 0.46$	$M=0.20 \pm 0.41$	$Z=-0.63$, $p=0.53$
Number of students answering "I do not know" or no response	$n=4$	$n=0$	$\chi^2(1)=2.25$, $p=0.13$
Do you agree with the statement: The progeny of antibiotic resistant bacteria is also resistant. Justify your answer.			
Number of students answering yes, with reasonable justification (e.g. "… resistance genes can pass along generations")	$n=11$	$n=18$	$\chi^2(1)=5.14$, $p=0.02$
Number of students answering yes, with confusing justification (e.g.".. bacteria are already 'born' that way")	$n=5$	$n=6$	$\chi^2(1)=0.00$, $p=1.00$
Number of students answering "I do not know" or no response	$n=9$	$n=1$	$\chi^2(1)=6.13$, $p=0.01$
Imagine that you have the flu, you are feverish and aching. In this situation, do you think that antibiotic prescription would be a suitable solution? Justify your answer.			
Number of students answering no (justification e.g. "… the flu is caused by a virus"	$n=7$	$n=17$	$\chi^2(1)=4.50$, $p=0.03$
Number of students answering yes (justification e.g. "…the antibiotic would relieve the symptoms"	$n=11$	$n=6$	$\chi^2(1)=1.23$, $p=0.27$
Do you think that bacterial infectious diseases are currently under control? Justify your answer.			
Number of students answering yes (justification e.g. "… because we have antibiotics to treat infections")	$n=14$	$n=4$	$\chi^2(1)=6.75$, $p=0.01$
Number of students answering no (justification e.g. "… bacteria can resist antibiotics")			
Number of students answering that it depends (justification e.g. "… some are, while others are not")	$n=5$ $n=5$	$n=17$ $n=4$	$\chi^2(1)=8.64$, $p=0.00$ $\chi^2(1)=0.00$, $p=1.00$
List measures that can be used to avoid or reduce antibiotic resistance.			
Number of students providing at least one correct notion	$n=9$	$n=22$	$\chi^2(1)=11.08$, $p=0.00$
Mean number of reasonable notions (e.g. "… do not use leftover antibiotics")	$M=0.56 \pm 0.87$	$M=1.72 \pm 0.94$	$Z=-4.16$, $p=0.00$
Mean number of unreasonable notions (e.g. "… use stronger antibiotics")	$M=0.40 \pm 0.50$	$M=0.12 \pm 0.33$	$Z=-2.33$, $p=0.02$
Number of students answering "I do not know" or no response	$n=6$	$n=0$	$\chi^2(1)=4.17$, $p=0.05$

After the project, most of the participants were aware of the meaning of antibiotic resistance (Table 1), which was perceived as a bacterium intrinsic feature transmitted along generations and potentially transferred among different bacteria species. This is interesting, especially given that a common misconception about antibiotic resistance is that it refers to a status of the person itself and not of the bacteria (Davey et al., 2002). The participants were attentive about bacteria's capacity to adapt to the presence of an antibiotic, by developing mechanisms to counteract its effect and allow them to survive ($n_{\text{pre-test}}$=4 vs. $n_{\text{post-test}}$=11, p=0.09). Furthermore, they also admitted that resistance can be transmitted along generations. When asked to comment whether or not the progeny of antibiotic resistant bacteria would also be resistant, most of them indicated that this can happen, as the genes involved in antibiotic resistance can be passed from one bacterium to its "daughter-cells" (Table 1). One participant even mentioned in the post-test that this process is designated vertical gene transfer. However, the participants seemed to confuse this notion with horizontal gene transfer. It has been argued that horizontal gene transfer is the most important mechanism in the dissemination of antibiotic resistance, by allowing resistance-associated genes to be interchanged between bacteria that may not be phylogenetically related but are subjected to the same antibiotic-induced selective pressure (Juhas et al., 2009). Taking this into consideration, this notion is emphasized in the project, by encouraging the participants to associate resistance with genetic traits, introducing them to the notion of plasmid, and asking them to mobilize this knowledge in thinking of ways in which bacteria can transmit resistance. The fact that this was not reflected in the participants' questionnaire responses indicates the need to revise the instructional design in future editions of the project.

Another common misconception about bacteria and antibiotics pertains to antibiotic use for flu treatment. This notion is known to be related with the belief that bacteria and viruses are identical microorganisms (Buke et al., 2005; Grigoryan et al., 2007; McNulty et al., 2007), and also with the profilactic prescription of antibiotics by the physicians to avoid latent and concomitant bacterial infections (Abbo et al., 2011).Throughout the week, the participants' opinion in this regard shifted from the belief that antibiotics are a suitable solution to treat flu ($n_{\text{pre-test}}$=11 vs $n_{\text{post-test}}$=6, p=0.27), to the perception that this is not a reasonable option ($n_{\text{pre-test}}$=7 vs. $n_{\text{post-test}}$=17, p=0.03). Some of them mentioned specifically that the flu is caused by a virus ($n_{\text{pre-test}}$=1 vs. $n_{\text{post-test}}$=5, p=0.22), and were concerned that incorrect antibiotic use in this regard may foster antibiotic resistance ($n_{\text{pre-test}}$=0 vs. $n_{\text{post-test}}$=10, p=0.00). The fact that the association between improper antibiotic administration and resistance was established by the participants themselves, is quite promising, considering that the use of these drugs for the treatment of colds and flu remains a common misinformed behaviour (Buke et al., 2005).

Beliefs about antibiotic use and antibiotic resistance

The data collected also point towards relevant changes in the participants' beliefs about infectious disease control and an increased consciousness of the urgency and type of measures to counteract antibiotic resistance. When asked if they thought that bacterial infectious diseases are currently under control, the participants' opinion changed from the belief that these are indeed contained (Table 1), mostly due to the existence of antibiotics and disinfectants ($n_{\text{pre-test}}$=13 vs. $n_{\text{post-test}}$=1, p=0.01), to the perception that emerging and re-emerging bacterial infection outbreaks are a major public health issue (Table 1), due to the occurrence of antibiotic resistance ($n_{\text{pre-test}}$=3 vs. $n_{\text{post-test}}$=18, p=0.00 and the difficulties in producing new antibiotics ($n_{\text{pre-test}}$=1 vs. $n_{\text{post-test}}$=5, p=0.13). The identification of this turning point in the warfare against infectious diseases, leads to an increased consciousness about the challenges presented by antibiotic resistance. This is of paramount importance to stimulate public receptivity towards the need to engage in rational antibiotic use (Alfonso, 2005; Davey et al., 2002; Grigoryan et al., 2007). In addition to this increased awareness about the impact of antibiotic resistance, there were also meaningful changes in the participants' beliefs about the personal endeavours that must be made to address this issue. This is particularly relevant considering the importance to foster self-responsibility and to increase the awareness for actions that can be explored to address resistance (Davey et al., 2002). Interestingly, prior to their participation, only nine students suggested that the effects of antibiotic resistance could be mitigated by decreasing antibiotic use and respecting usage instructions. Seven students actually thought that developing new drugs or using different antibiotics were the best or probably the only available solutions. Conversely, following the activities, almost all students (Table 1) highlighted the importance of responsible behaviours, such as using antibiotics only when necessary ($n_{\text{pre-test}}$=5 vs. $n_{\text{post-test}}$=18, p=0.00), and following the physicians' recommendations ($n_{\text{pre-test}}$=2 vs. $n_{\text{post-test}}$=17, p=0.00). The investment in drug development was not dismissed, but it was no longer regarded as the only option, which suggests that the participants are sensible about the importance of individual decisions. Furthermore, while in the beginning of the project there were six participants who did not indicate a single mitigation measure, at the end all of them mentioned at least one. In fact, there was a significant increase in the number of alternatives presented by the participants (Table 1).

Participants' feedback on the project

Overall, the participants enjoyed their participation in the project. As depicted in Table 2, they were very satisfied with the activities, the organization of the contents, and the articulation between techniques and theory presented. They did not find the techniques too difficult, but considered that the success of the tasks proposed required effort. Moreover, they reported that the project contributed to enhance their curiosity and understanding of the issues discussed, and their capacity to critically reflect about those issues (Table 2).

Table 2. Participants' appreciation of the project.

Rate the following aspects on a 1 (Very low) to 5 scale (Very high)	
Difficulty of the contents (M=3.12, SD=0.67, t(24)=0.90, p=0.38)	Contribution to understand the issues discussed (M=4.56, SD=0.65, t(24)=11.99, p=0.00)
Interest of the contents (M=4.44, SD=0.51, t(24)=14.21, p=0.00)	Contribution to critically reflect about the issues discussed (M=4.44, SD=0.58, t(24)=12.35, p=0.00)
Organization and structuring of the contents (M=4.29, SD=0.81, t(24)=7.85, p=0.00)	Contribution to enhance the curiosity about the issues discussed (M=4.56, SD=0.77, t(24)=10.16, p=0.00)
Difficulty of the techniques (M=2.96, SD=0.90, t(24)=-0.23, p=0.82)	Overall satisfaction about the project (M=4.24, SD=0.72, t(24)=8.57, p=0.00)
Articulation between content and techniques (M=4.40, SD=0.76, t(24)=9.17, p=0.00)	
Suitability of materials used (M=4.44, SD=0.82, t(24)=8.77, p=0.00)	
Effort required (M=3.36, SD=0.81, t(24)=2.22, p=0.04)	
Indicate the…	
… most positive aspects (open question)	… less positive aspects (open question
"… learn more about this topic…" (n=12)	"… the theory…" (n=5)
"… improve my laboratory skills… " (n=6), …	"… waiting for the results…" (n=3), …
Make any comments or suggestions you consider necessary (open question)	
"I really enjoyed this project. It was very useful and fun", "I think that activities should continue", …	
Evaluation of the project (1-Mediocre to 5- Excellent) (M=4.36, SD=0.87, t(24)=11.96, p=0.00)	

The participants were particularly pleased about the chance to learn more about the topic and improve their laboratory skills (Table 2). In contrast, the amount of theory presented was pointed out as the major negative aspect of the project (n=5, Table 2). In this project, a major concern is that the theory is aligned with practice and presented it in an appealing way, namely by prompting group-discussions. Even so, it is possible that these participants were expecting a less serious, more entertaining scenario, since they were in the summer holidays. University of Porto's Junior University can be considered an educational leisure context, in the sense that it seeks to promote learning and education in a relaxed, engaging environment.

Therefore, as argued in research focusing on these contexts, some visitors may be more motivated by the expected social experiences than the learning opportunities (Packer & Ballantyn, 2004).

CONCLUSIONS AND IMPLICATIONS

This study evidences the efficiency of a hands-on project to promote informed decision making about antibiotics, by indicating the possibility to interfere with high school students' perceptions and behavioural intentions regarding antibiotic use. The data gathered demonstrate that the participants became more aware of the perils of antibiotic resistance and of the importance of individual choices in this context. The participants' feedback also revealed that they value being given information about these topics through active learning strategies based on practical work. However, this was a small scale study involving high school science students. Therefore, in spite of the statistically significant results obtained, it would be useful to extend this research to populations from different age groups and instructional levels, with diverse curricular backgrounds. The project's modules can be implemented in school settings, by recombining the activities. Moreover, the materials and equipment required are affordable and easily available, and the techniques involved in the procedures are relatively straightforward. The formal implementation of this project would strengthen the evidence of its effectiveness and assist in overcoming biases introduced by sampling students who actively enrol in these activities (Lohr, 2009). Accordingly, from January to July 2011, two of the modules included in the project ("*Natural antibiotics: garlic's antibiotic properties*" and "*A bioinformatic approach to the evolution of antibiotic resistance*") were implemented in seven 12th grade biology classes (4 experimental and 3 control groups) from four secondary schools in Porto. Furthermore, similar initiatives will continue to be implemented in informal contexts, including Porto's Junior University's future editions. Particular attention will be paid to the activities' impact on the participants' awareness about the personal and societal implications of antibiotic use and resistance.

ACKNOWLEDGEMENTS

The authors are grateful to all the participants and to Porto University. MJF and CLS are supported by the Fundação para a Ciência e a Tecnologia fellowships SFRH/BD/37389/2007 and SFRH/BPD/62978/2009, respectively.

AN ANTHROPOLOGICAL APPROACH TO ANALYSE A CHEMICAL KNOWLEDGE DURING EXPERIMENTAL DESIGN

Isabelle Girault, Cédric d'Ham, Mohammad D. Alturkmani, Hamid Chaachoua
IMAG, Université Joseph Fourier, Grenoble, France

Abstract: In the context of experimental design, students have to write the procedure of an experiment. For this purpose they need to reuse and adapt existing procedures. We studied the procedures produced by students to answer a chemical problem of titration by spectrophotometry. We analysed the content of the written procedures with the Anthropological Theory of the Didactic. This facilitated the analysis of the strategies used by the students, and specifically when the procedure is not satisfactory. To be successful, it is necessary for students to understand the knowledge underlying an experimental task, *i.e*. to relate the technological level to the technical level. We illustrate this with examples.

Keywords: Anthropological Theory of Didactics, Labwork, Experimental design, Chemistry

1) Background, Framework, and Purpose

Experimental design

The experimental design is considered in the context of the broader activity of the experimental process: a subject has to solve a scientific problem through experimentation. During this process, students have to design an experiment to answer the scientific problem. Different studies emphasize the importance of designing an experiment in a learning context. Neber and Anton (2008) observe higher-order cognitive activities (thinking) of students facing such a task. Arce and Betancourt (1997) find that students show better understanding of concepts related to the experiments they designed themselves.

The Anthropological Theory of Didactics, ATD

The Anthropological Theory of the Didactic (ATD) puts forward a model of mathematical activity (especially including school mathematical activity) in terms of praxeologies (Chevallard, 1999; Rodriguez, Bosch, & Gascon, 2007). Even if it was first described in the domain of mathematics, this theory can be applied in other contexts. We will use it to analyse the chemical knowledge during an activity of experimental design in Chemistry.

The general epistemological model provided by the ATD proposes a description of mathematical knowledge in terms of mathematical praxeologies whose main components are types of tasks (or problems), techniques, technologies and theories. The most elementary mathematical praxeologies consist of a practical block or “know-how” (the praxis) integrating types of problems and techniques used to solve them, along with a theoretical block or “knowledge” (the logos) integrating both the technological and the theoretical discourse used to describe, explain and justify the practical block. Thus any “piece of mathematical knowledge” should be described through the statement of what kind of mathematical problems and techniques are involved and what kind of description and justification is given to this “way of doing”.

The objective of this study is to understand what knowledge (logos) the students use when they design an experiment in analytical chemistry.

2) Rationale

This study is part of a larger one that aims at defining the key features of environments devoted to the scaffolding of learners engaged in experimental design (d'Ham, Girault, & Mandran, 2009). The software, copex-chimie (see Fig. 1) used during the current study, is a web-application (http://copex-chimie.imag.fr/) in which the learners have to determine the concentration of the red dye in a grenadine syrup by spectrophotometric titration (d'Ham, de Vries, Girault, & Marzin, 2004). To attain this goal, students must specify an experimental procedure that will be simulated by the application. An artificial tutor is accessible on demand to the learner. This artificial tutor evaluates the procedure, step by step, following a constraint-based system, and it points out the errors to the learner.

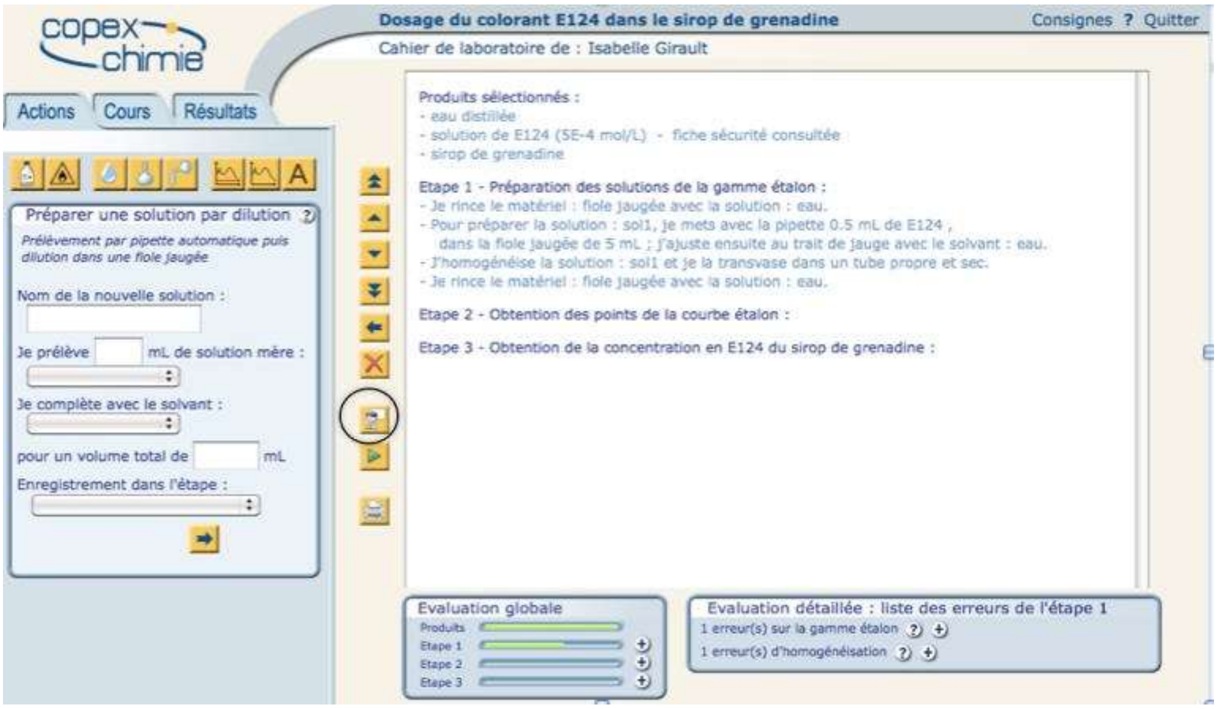

Figure 1: Interface of copex-chimie. The automatic tutor has been requested (see circle) and the bottom right part shows the evaluation given by the tutor.

This chemistry labwork ("determine the concentration of a substance in a solution") refers to design problems (Apedoe & Ford, 2010) where the problem is already given to students and there is no need to formulate hypothesis. The students have to concentrate on the design of the experiment and the analysis of the data to conclude (they do not have to perform the experiment since they obtain their data by simulation, according to the procedure they have described). The general organisation of the procedure is imposed on the students by the structure of the environment, however they have to adapt to and instantiate it. This means that they have to define the low-level tasks of their procedure.

If we use the ATD model to describe the tasks of this experiment, here is an example of praxeology (see Fig. 2). A type of task is "choose a solution to wash the material". In the context of this labwork, an appropriate technique to solve this type of task is to wash the glassware (*e.g.* volumetric flask) with the solvent if it is used to prepare a solution by dilution (or dissolution). The technology that justifies this task is the knowledge about the concentration. For example, when preparing a diluted solution of the dye E124, if the volumetric flask is washed with the E124 solution, the concentration of the final solution will be higher than expected.

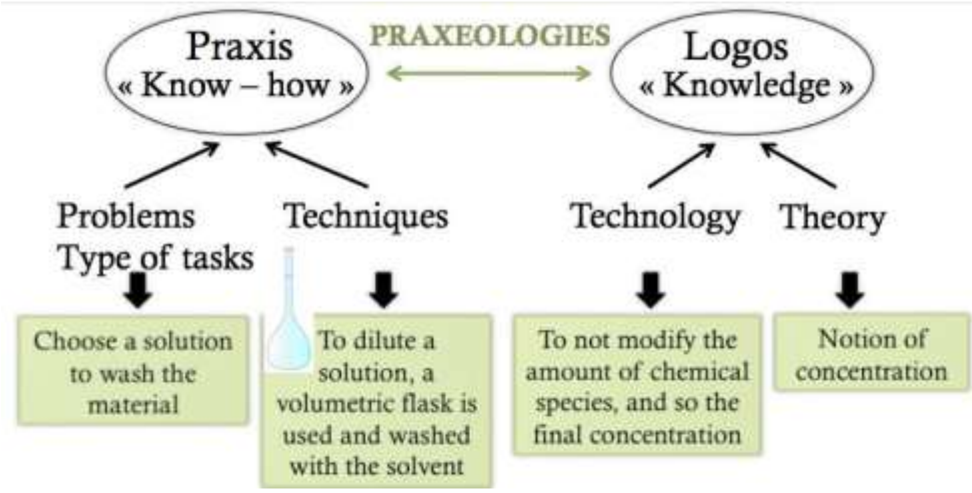

Figure 2: Detailed example of a praxeology corresponding to the task "choose a solution to wash the material (volumetric flask).

The question addressed by this study is the following: Among the praxeologies involved in this labwork, which ones are difficult to handle for the students? The overall goal of this study is the adaptive feedback of copex-chimie.

3) Methods

We first described the reference praxeologies that are the praxeologies expected from the teacher. Then we analysed the praxeologies used by each student and compared them with the reference ones. When a difference existed (it corresponds to errors in the procedure written by students), we checked if the students used a particular technique based on a personal technology (that could eventually be the consequence of a misconception).

Trials with copex-chimie were performed at the University of Grenoble in January 2010 with 103 first year university students. The students worked alone in a computer room during two hours. The teacher briefly presented the work to be done with copex-chimie and then let the students work independently. Log-files containing the activity of the learners during the session were recorded. From these log-files, indicators were extracted to describe the students' work with copex-chimie. These indicators were based on the tutor's evaluation. For example, the tutor indicated that a student did not wash the glassware with the appropriate solution. To better understand the praxeology of this student, we delved more deeply in the log files to have more information (*e.g.*, it is interesting to know which inappropriate solution was used).

4) Results

We present in the table below part of our results.

Type of task	Appropriate technique in the context of this labwork	Technology (justification of the appropriate technique)	Students who did not use the appropriate technique	Students who used a specific inappropriate technique
			(Number of students / total number of students concerned)	
Choose a solution to wash the material (volumetric flask)	To dilute a solution, wash the volumetric flask with the solvent (water in our case)	To not modify the concentration of the solution to be prepared	23 / 103	9 / 23 (Use of E124)
Choose a solution to wash the material (cuvette)	The cuvette needs to be washed with the solution that will be used as a sample (solution of E124 in our case)	To not modify the concentration of the measured solution	63 / 103	51 / 63 (Use of H_2O)
Choose the concentrations of the calibration curve solutions	Calculate an approximate of the highest concentration that belongs to the linear part of the calibration curve (C<Cmax), by using the given order of magnitude of epsilon. Then prepare solutions that are below Cmax.	Beer-Lambert's law is only applicable in a certain range of concentration	42 / 103	32 / 42 (use of a common technique instead of calculating Cmax)
Choose the standard solution for the calibration curve	Choose the known concentration (E124 dye in our case) of the species to be measured in the "unknown" sample.	This will allow to plot the curve A = f(C)	45 / 103	39 / 45 (use of the grenadine syrup)

When students use an inappropriate technique, it is interesting to understand why they used such a technique. For example, for the type of technique "choose the solution to wash the material", most students use the appropriate technique when it concerns the volumetric flask. However, when the same type of task is used in another context (wash of the cuvette), 51 students (out of 103 students, 50 %) use H_2O instead of a diluted E124 solution. This result tends to show that some students use a technique automatically without understanding the technology behind (the justification of the technique) since in the case of the cuvette, H_2O has an influence on the chemical system.

Another interesting example illustrates the same idea that students tend to use a technique without understanding the conditions of its application. It concerns the type of task "Choose the concentrations of the calibration curve solutions". The only information the teacher told the students before they work by themselves with the computer environment was 'to calculate the concentrations of the solutions of the calibration curve you need to know the range where the concentration and the absorbance are proportional. For this, you need to calculate the maximal concentration that corresponds to this linear part'. The result shows that 32 students (out of 103 students, 31 %) chose concentrations made with the following volumes of standard solution: 1 / 2 / 3 / 4 / 5 mL (or very similar to this). Even with the instruction given by the teacher, they did not feel necessary (or did not know how to do it) and instead chose a regular technique used in the classroom, which consists on making dilutions with volumes from 1 to 5 mL. However the standard solution has such a concentration here that all these dilution have a concentration higher than Cmax.

The last example concerns the choice of the standard solution for the calibration curve. The students should use a solution of E124, which has a known concentration. Instead, 39 students (out of 103 students, 38 %) use the grenadine syrup as a standard solution. Apparently these students did not understand the principle of a calibration curve, that can not be plotted if the concentration of the solution is unknown.

5) Conclusions and Implications

The results show that in some cases the students use a known technique, that is efficient in some contexts but appear to be inappropriate in the current labwork. We believe that if students were more often confronted to experimental design, they would be forced to think about the techniques they use and consequently deal with the technology part. This corroborates the findings of Neber and Anton (2008) that students would show higher-order of cognitive activities.

The analysis of the knowledge with the ATD model allowed us to make a fine-grain diagnostic of the difficulties students encounter and better adapt the appropriate feedback. These feedbacks could be at a technique or technological level, depending on the importance of the task in the learning process.

DO PHYSICS TEXTBOOKS PROMOTE CONCEPTUAL UNDERSTANDING?

Hendrik Härtig[1] & Hans E. Fischer[2]
[1]IPN – Leibniz Institute for Science and Mathematics Education, Kiel
[2]University of Duisburg-Essen

Abstract: As in many other countries, there is a shift in Germany from input (curricular) oriented to output (standards) oriented science education (Schecker & Parchmann, 2007; Nentwig & Schanze, 2007). Thereby the intended curricula contain less content. As this takes place, other curricular materials—like textbooks—become more important for teaching as teachers use them to develop their implemented curriculum (c.f. Valverde et al., 2002). Van Eijck and Roth (2008) point out that teachers use textbooks to guide them in choosing and structuring topics for teaching; they also follow the depth or broadness of specific content in the textbooks while planning lessons. Due to the increasing importance of curriculum materi- als, we analysed physics textbooks concerning their content coverage and content structure using concept maps. Goal of the presented study is to prove whether physics textbooks pro- mote this development of conceptual understanding or whether they present fragmented knowledge pieces.

One result is that almost 90 % of the terms in the analysed textbooks are used only once or twice throughout the entire textbooks. As we were able to show, the textbooks' content covers huge areas but they are only weakly connected. Based on our results it might be argued that the textbooks do not promote conceptual understanding. They instead concentrate on factual knowledge, and even the important terms—seen from a graph-analytic point of view—are rarely used to connect different content areas. As the textbooks fail to develop a coherent con- tent structure which provides conceptual understanding of physics, one might argue that be- sides competence standards a core curriculum is needed. It would promote concepts that are highly important and lead to a similar knowledge that is usable in many different contexts.

Keywords: textbooks, conceptual learning, curriculum, concept map

BACKGROUND

In the most countries, the composition and structure of taught science knowledge in schools is defined on a political level through a curriculum (Valverde, Bianchi, Wolfe, Schmidt, & Houang, 2002). However curricula are exactly called, there is a general worldwide trend from content oriented curricula (input orientation) to competence based so-called standards (output orientation) (Nentwig & Schanze, 2007; Kauertz, Neumann, Haertig, in press). The decrease of content described in those *intended* curricula might be one reason why most teachers do not use curricula to organize their teaching (Loewenberg Ball & Cohen, 1996).

Textbooks contain a subject area's entire base of knowledge that should be taught in schools, and they present this knowledge in a structured way, depending on different contexts or edu- cational levels. Additionally the content of the books is aligned with the curricula in most cases as authors of textbooks are required to orient their work to the curricula (Valverde et al.,

2009). Teachers in many countries use textbooks to prepare their lessons, for example to de- cide what content to teach and how to present it (Schmidt, McKnight, & Raizen, 1997); they also follow the depth or broadness of specific content in the textbooks while planning lessons (Van Eijck & Roth, 2008). Textbooks may therefore be seen not only as *potentially imple- mented* curriculum, but *actually implemented* curriculum.

Learning materials—such as textbooks—have the potential to support learning, especially conceptual understanding as the number of learned correct associations according to a specific term is highly correlated with the frequency of this term's occurrence in the stimulus text (Shavelson, 1971). This may be explained from a psychologist point of view as the meaning of a 'concept' arises through associations (Johnson, 1964). So through reading and learning associations between the different 'terms', 'terms' grow into 'concepts'. The associations that are built depend on the learner and the used materials. Therefore it makes sense to take a closer look at textbooks and the content they present and how the content structure is pre- sented.

Content analyses of textbooks are typically based on specific coding units like ‘concepts’ as described by Shavelson (1971), ‘major themes’ or ‘key ideas’ in the sense of Chiappetta, Fillman, and Sethna (1991), or ‘ideas’ as Roseman et al. (2010) have done. These coding units seem to be of a different size: An example of a concept is *‘force’*; for major theme or key idea *‘the knowledge of science’;* and for an idea *‘Plants transfer the energy from light into energy-rich sugar molecules’*. We would like to argue with respect to theories of learning (e.g. Johnson, 1964), that ‘terms’ are the smallest unit that a learner would be confronted with. As textbooks are resources for learning and students have to build cognitive structures to develop conceptual understanding, the books should promote this.

A review on existing studies on textbook content concerning Nature of Science shows that textbooks do not cover all the content they should (Chiappetta, Fillman, and Sethna, 1991). Nehm et al. (2008) examined the usage of specific important terms throughout biology textbooks, and they found even these important terms are strictly bound to specific topics. Other studies have shown that today’s textbooks contain a huge amount of different terms without facilitating the learning of the larger ideas (Budianski, 2001). However there is a lack of studies on the whole content of textbooks using a reliable and valid way of coding the content structure. Within our study, we have developed a reliable and valid method to code the whole content structure from physics textbooks as concept maps, which allows different quantitative analyses of the presented content (Haertig, Neumann, & Fischer, submitted).

METHODOLOGY

This study concentrates on the structure of content presented in physics textbooks. Concept maps are suggested for textbook analyses due to the possibility of analyses using graph theory approaches (Borgatti and Everett, 2005). Moreover, this method makes it possible to analyse the content of whole textbooks, which is needed to determine if and how textbooks foster students’ learning.

Borgatti and Everett (2005) provide an overview of different parameters that can be taken into account for analyses of the terms in maps. Degree centrality equals the number of a term’s incoming and outgoing propositions. Based on Shavelson (1971), this parameter provides information about how well the term may be connected in the mental representation of the learners’ content structure. The length of a path as closeness-like measures is the number of steps that is needed to reach one term from another one, while one step is a proposition that connects two terms. In comparison the betweenness centrality does not start with a specific term. Based on other analyses, how often each term lies on the shortest paths can be counted. Both measurements can be seen as ability to connect other terms (Borgatti and Everett, 2005).

Four books were chosen to be analysed; these books are widely used by schools and representative of the widest variance of physics content based on interviews with the publishers. All of these textbooks include grades seven to ten. A guideline for textbook analysis was used to guarantee a reliable, valid and objective procedure (Haertig, 2011).

RESULTS

Two results from other studies have been reproduced: The number of coded terms per book is very high in this study and most terms have a low coverage throughout the textbooks (Haertig, Neumann, & Fischer, submitted). Within our study we could find, that a typical physics textbook contains between 714 and 890 terms with up to 2413 propositions on about 350 pages. The average number of connections per term is 5.8; the average number of terms per proposition is 2.9. Each page of the textbook contains statistically 2.2 newly mentioned terms and 4.3 propositions. In approximately 15% of the propositions, only one term is mentioned, meaning that there are no connections to other terms.

The degree centrality, which is the parameter with the closest relationship to Shavelson's (1971) work, follows an exponential function. So, there are very few terms with a high degree centrality and many terms with a very low one. This is the same for all four books. Furthermore we were able to find a high correlation between degree centrality in the four different textbooks. All four books have in common that most terms (~90%) have a degree centrality of one, which means they are used within exactly one proposition; meanwhile those with the highest centrality are almost the same in all of the textbooks. In a general sense, the other parameters lead to similar results. The analyses show that many of the terms have low values for betweenness centrality, closeness centrality and for the linkage parameter. Very few terms have high values for all parameters. Table 1 shows the 10 terms with the highest values for each of the four parameters.

Degree	**Closeness**	**Betweenness**	**Linkage-Parameter**
Body	Body	Body	Body
Force	Energy	Energy	Energy
Energy	Electron	Electron	Force
Electron	Force	Voltage	Voltage
Voltage	Voltage	Force	Current (phen.)
Current (quantity)	Current (phen.)	Light	Temperature
Light	Light	Direction	Current (quan.)
Resistance	Time	Current (phen.)	Direction
Current (phenomenon)	Direction	Resistance	Light
Inductor	Material	Material	Electron

Table 1: Terms ordered by centrality and linkage-parameter

Even if the different centrality indices correlate on a high level, they are not completely equal. Therefore, some important terms have different functions for the content structure (c.f. Carley, 1997): Some might be better used to connect different topics since they have lots of propositions with different topics. Other ones might be used to build hierarchical connections in a sense of vertical linkage within the content structure as they can be found on many shortest paths. Within our study we could find a correlation between the different parameters on a mediocre level (.265 < Pearson's r < .535; p < .001).

Additionally we could find that most terms have low coverage within the textbooks. Textbooks typically are ordered into chapters like "mechanic", "electromagnetism", or "optics". Only seven terms are used in all topics: time, earth, body, direction, material, gas, and liquid. In comparison to the table above, body is the only term that has high values there, too. Surprisingly, "energy" or "force" cannot be used to connect the chapters' content.

DISCUSSION

Through the use of concept maps, it is possible to identify scientific terms and propositions as they are likely taught. This provides a deeper understanding of the underlying structure and the relationship of physics terms as foundations of students' knowledge. Teachers and researchers should reflect very deeply on the content presented in the textbooks. As we were able to show, the textbooks' content covers huge areas using hundreds of terms but they are only weakly connected. Hence, lots of terms are used very rarely, and the importance of teaching each topic in detail should be debated. It seems as if a broader view and more interconnections between the different topics would be possible with a smaller total amount of terms. Based on our results it might be argued that the textbooks alone do not promote conceptual understanding. They instead concentrate on factual knowledge, and even the important terms—seen from a graph-analytic point of view—are rarely used to connect different content areas. On the one hand, it is encouraging, that 'concepts' like "energy" or "force" get high values in the graph analyses; on the other hand they could be mentioned within all topics—in optics as well as in mechanics—if they are really seen as anchors for a deeper conceptual understanding.

Due to the results a discussion of what comprises a 'concept' could be based on objective data. Comparable to Carley's (1997) work, it should be possible to build groups of terms with common characteristics based on the different centrality measures. Perhaps one of those groups would then be called 'concepts' as they have a high coverage within the textbooks and are able to easily connect different topics. This idea might be connected to what we know from conceptual learning: Learning physics starts with intuitive (naïve) ideas that the students already have based on all-day life experience. This knowledge is highly robust and very fragmented, which leads to problem specific solutions based on surface features (e.g. Hammer, 1996; Chi & Slotta, 1993; Chi, Feltovich, & Glaser, 1981). Besides being taught about the science physics there is no specific reason for students to 'forget' their intuitive ideas. Therefore either from a misconceptions or a p-prims point of view lot of effort has to be spent to deconstruct the misconceptions or refine and integrate the p-prims (c.f. Taber, 2008; Sabella, 1999; diSessa, 2008). This can be seen as learning progression (in sensu Liu & McKeough, 2005), which is as well dependent of general age-dependent abilities as of well organised curricula, well prepared teachers and last but not least well designed curriculum materials.

By taking both into account, learning of conceptual knowledge and our results from the textbook analysis, we would like to state that today's (German physics) textbooks do not support conceptual understanding. Therefore they would have to focus on a core of knowledge which might be based on those terms, which serve as concepts from an expert point of view. For this reason a core curriculum could be a really helpful supplement to the already existing standards from our point of view as it will guide the teachers through developing their own implemented curriculum. Terms and relations for such a core curriculum may be found by applying the concept mapping method presented within this study and deleting those 90 % of terms which are used only once or twice, concentrating on terms that are highly connected and their relations among each other.

INFORMAL LABORATORIES AND PUPILS' REASONING IN INTERPRETING ELECTROSTATICS INTERACTIONS

Alessandra Mossenta[1] *and Marisa Michelini*[1]

Physics Education Research Unit of University of Udine

Abstract Research in secondary school shows that it is particularly difficult the interpretation of simple phenomena of electrification and charge transport. The lack in simple charge interaction phenomena analysis appears to be important. We therefore organized activities of experimental exploration to support the building, from primary school level, of the concept of charge and its properties as guided reflection on macroscopic experiences. Informal and ludic approach appears to be useful in spontaneous reasoning analysis. In the context of the hands-on exhibition Games Experiments Ideas (GEI) in Udine and in Crema (MediaExpo 2009) were offered to pupils of 10 primary schools classes Conceptual Laboratories for the Operative Exploration (CLOE) on charge processes for phenomenological explorations in the light of the discussion of interpretative hypothesis. The process of building the interpretive reasoning of the phenomenology is explored and analyzed by means of the recording of small group discussions, interviews and stimuli cards/worksheet. The transition from a spontaneous vision of phenomena to a scientific one is the main focus of the analysis. The analysis of material collected during the activity provides information about students reasoning in interpreting the processes of charging.

Keywords Electrostatics; charge; primary school; reasoning; interpretation.

INTRODUCTION

Background, Framework and Purpose

Electrostatics offers many interesting aspects in developing scientific reasoning and formal thinking. It is the area where the electric nature of matter and some main concepts of electromagnetism (charge, potential and electric field) are built. It offers the opportunity to contextualize some constraints framing the subject content of physics: the principle of conservation (of the charge), the superposition principle, the concept of dynamic equilibrium. From a methodological point of view, electrostatics offers opportunities for exercising logical inference with regard to the conclusions that could be drawn from an analysis of macroscopic states and processes for the construction of reasoning aiming at an interpretation of the microscopic world: from changes observed at the macroscopic level after specific actions, evidence is obtained supporting the existence of the charge as an internal, mobile and twofold property of matter. This process is an example of scientific ways of looking in the study of phenomena and illustrates how science builds its hypothesis. Interest of science education research for electrostatics arises also from the problem that the lack of connection between electrostatics and electrodynamics is the basis of specific learning difficulties in this field (Eylon, 1990). The students' macroscopic description of electric circuits is not linked to the microscopic quantities introduced in electrostatics. Other authors pointed out that previously acquired knowledge in electrostatics is re-used in the context of circuits in an unchanged form, without adapting it to the new context (Benseghir, 1996). Part of the students' reasoning in electrokinetics come from a conceptual basis which includes a more or less intuitive knowledge of electrostatics, using the concept of electrical charge instead of the more abstract concept of potential difference in the analysis of the circuits. The students' focus is on the charges that they ascribe to the ends of the battery. Following these conclusions, specific interest arose for the reasoning in electrostatics. Research on learning difficulties in electrostatics can be divided into two areas. Some studies were carried out about the more formalized aspects of the electric field, Gauss law, electric potential (Törnkvist, 1993; Rainson, 1994; Viennot, 1999; Furio, 1998, Maloney, 2001), focused on high school or university students. Other studies are focused on the basic phenomena helping to build the first electrostatic interpretation: the process of electrification of bodies by friction, contact or induction and charge transfer (Guruswamy, 1997; Furio, 2004; Zubimendi, 2005; Guisasola, 2008). Again the involved students are in high school or university. We conducted inquiries at lower age (GEI) (Michelini, 2007) confirming the assumptions made for older students (Furio, 2004) on the spontaneous use of models already historically emerged during the development of the theory. The results of these studies show that simple phenomena of electrification by friction and induction are interpreted by the students according to four main models: Creationist, Halo-effect, Fluid, Newtonian. After researches on how electrostatics is learned, teaching/learning sequences and strategies are being developed to go beyond learning nodes that lead students to non-scientific conceptions (Guisasola 2008). The persistence, in spite of schooling, of these non scientific models leads us to suggest the anticipation of phenomena exploration and the reasoning analysis for conceptual change process. This to exploit the attention to the phenomena that is part of the natural curiosity of children, and to avoid rooting of the interpretative models of common sense, consolidated and reused in several experiences (Viennot 1999, Michelini 2004). Following empirical studies on teaching/learning paths about basic electrostatic phenomena (Zubimendi 2005, Michelini 2007, Guisasola 2008, Mossenta 2010a and Mossenta 2010b) a proposal was designed, according to a vertical path from primary to secondary school level.

We present a research study carried out in a CLOE (Conceptual Laboratory for the Operative Exploration) context with 114 students of primary and middle school, during open informal activities offered to schools. The research is aimed to study spontaneous reasoning in context of emblematic situations and the reasoning evolution during games proposed for charge processes exploration.

Rationale

The study refers to a module of activities proposed to pupils. All activities are offered in a consistent and comprehensive way as a framework for exploration. The rationale of the intervention module aims to build the concept of charge as property acquired by the objects, after a preparation that makes them be in a state allowing them to interact in different ways by virtue of the property. All ways are based on two types of property, produced by entities necessarily always present inside the objects, that can be activated in different ways and responsible of the electrical interactions. These entities can move in the objects and from one object to another and keep unchanged their total amount. Some steps are stated for developing this interpretation process: from the simple observed interactions to the concept of charge as a state property of prepared objects. Our study aims to inquiry if it is possible to drive pupils to a construction of the interpretative framework through experimental exploration of different ways of electrifying objects, focused on the macroscopic properties of the electrical interactions. The proposed situations involve adhesive strips pulled from the same area, to recognize a property (repulsive effect) acquired from the tape as a result of the pulling; objects as plastic labels and straws rubbed with the same material, to generalize the situation; the same systems, but prepared with different materials, to recognize attraction and repulsion as different ways to interact, characterizing the property of the interacting systems accordingly; systems pulled or rubbed together, for a first introduction of the conservation of the charge.

We studied the extent to which children's reading of experiences involves identifying aspects scientifically relevant, descriptive and interpretative, according to the purposes for which the experiences were proposed. The research questions were therefore as follows:

RQ1: In what terms pupils read the behavior of the observed systems: descriptive or interpretive, according to a vision that considers the whole system or stops at a local view centered on the individual components?

RQ2: Do pupils identify the action that changes the state of systems? And that this will change the way they interact with other systems?

RQ3: Do pupils identify elements of explanation of the systems behavior? What are these elements? What are their features?

The underlying macro problem is the role for the learning of the proposal in its different aspects: cultural, cognitive, conceptual, methodological and operational. We studied the possibility of activating in the children interpretative tools, as reasoning looking to states and processes or closed logic and consistent inferences grounded on the experienced phenomena.

METHODS

In the first part of the proposal, tested in CLOE sessions, stimuli explorative cards are used (Martongelli, 2001; Michelini, 2004) helping to record ideas, and a strategy of Situation-Prevision-Experiment-Analysis, SPEA (Michelini, 2009): the presentation of a situation to the pupils, their justified prevision about its evolution as a result of a specific action, the experience and an analysis of the outcome compared to the prevision, referred to the reasons previously expressed. The activity involved primary school classes (10, fourth and fifth classes) and 1 middle school class: 114 pupils aged 9-11. It was conducted in small group sessions for an hour; the interpretation of experiences of charging by pulling/rubbing was proposed, and children individually filled the cards after the experiences and discussion on them. The analysis of these data allowed to keep track of the processes put in place during that activity. The answers written by the pupils on the worksheets were classified according to categories, related to the purpose of each step; they were defined a-priori from literature and previous activities and re-defined a-posteriori with the aid of the audio-recorded answers in interviews and discussions, to detect the pupils' ideas and the kinds of explanations after each experiment, and the evolution of ideas and explanations during the activity.

RESULTS

Following the first experience, in which two strips of adhesive tape were approached after being pulled from the same place, all pupils identified a change in the state of the system observing the changed behavior of the pulled strips. Asked to specify the observed behavior, pupils gave answers that can be classified in two categories: I) descriptive (71/114 pupils), and II) interpretative ("they repel each other"/ "They do not attract each other"43/114 pupils). The descriptive category (I) refers the movement observed in the strips according to two subcategories: Ia) a single system whose parts changed their respective positions, "the tapes went away one from the other" (58/114 students), Ib) two separate systems that are deformed, "the tape is bent outward (13 pupils of fifth class). After the later experience of rubbing plastic labels and straws, most of this group changed the answer (11 out of 13 pupils) and claimed that the two observed systems went away one from the other: they maintained a descriptive view, but gained a more global perspective during the different explorations. The pupils of the other categories maintained their first way of looking at the phenomena during the different experiences proposed to them.

After observing the system behavior of the two tapes, pupils were required to identify the actions producing the observed behavior: almost all pupils (108/114) described actions related to the observation of system behavior, without being precisely the conditions that produced it: they are sometimes records of observed actions. These are the mechanical actions performed on the tapes (attacking/pulling off the strips) and their approaching after their pulling (bringing tapes one near the other); the action of pulling is identified as the triggering action by 88/114 students. The interaction with the table (attaching) is focused by a few (19) pupils. Almost as many pupils consider only the action making the state visible (approach) and not the action that produces that state (13 pupils out of 54 citing it). Very few (3/114) pupils cite all the actions responsible for the activating of the tapes. In a fifth class, 6/13 pupils use interpretative quantities and a model of supply when asked about the action performed on the tapes: “maybe we gave it the energy" / "we gave electricity with the strong pulling". This change of level is not repeated dealing with the following experiences.

Coherent explanations of what produces the behavior of the tape are given by 75/114 pupils. The interpretations are based on two kinds of elements: a) proper of physics or pseudo-physics (84): force, energy, electricity, B) proper of the context (18): process variables noted, such as materials or the procedure used to change the status of the observed systems. 58 pupils relate the explanation to the action of activation, according to 4 categories of elements of explanation: a1) materials and activation mechanism (10 explanations, 3 involving a mechanism: “it takes something from the material”); a2) energy (taken during the pull, 24); a3) electricity/charge (taken or created or produced during the pull, 23); a4) the action of pulling (1); 26 pupils link the explanation to the observed interaction: 25 pupils attribute the interaction to a force, magnetic for 23 of these (“because there is a magnetic force”), only 1 pupil claims a description; 18 pupils relate the explanation to contingent factors (heating, gravity, the glue). In the fourth classes the explanation (one for each pupil) is mostly based on a interpretative quantity (7 pupils do not respond, 18 use the idea of force), in the fifth classes explanations become complex and the explanations are based on several factors: "the glue that is here, magnetism, a kind of energy, electricity is created in the pulling". The same question proposed after the experiences involving different objects and ways to activate them produces a cue about the coherence of explanations: 10/73 pupils modified their explanations, changing the involved entity (6) or introducing the preparation or the change of state as explanation (4). 5/73 pupils enriched their explanations with a mechanism regarding the same explaining entity; 12/15 students of the same class modified the explanation after experiencing the action of rubbing plastic labels, saying that "there is something inside the label". A final discussion into a group of 11 pupils of 4th and 5th class confirm that pupils recognized the involvement of two objects in every experience; that the observed 2 behaviors of the systems were produced by the action of pulling or rubbing, the condition on the objects to obtain these behaviors, in terms of preparation: “When you do the same thing they repel each other, when you do not do the same thing they repel or attract each other”. After the activity 16 pupils of 5th class and 13 of 4th class were asked to tell to a friend what is happening in 2 situations, proposed by two pictures of adhesive tapes repelling and attracting, and to explain him/her what happened in the tapes to produce these behaviours. 14/29 pupils express an explanation, 7 of them involving charge or energy (“In fig. a) the tapes attract because in one there is a positive charge and in the other negative. In fig. b) they go apart because the charges are both negative”), 6 referring to a preparation linked with the experiences seen (“In fig. a) the tapes approach because they were rubbed together. In fig. b) they go apart because they were pulled off the same material”), 1 referring to contingent and anmistic causes; 3/29 pupils give an interpretation in terms of interaction without elements of causality ("In fig. a) the tapes attract and in fig. b) they repel"); 12/29 pupils only describe the behavior ("In fig. a) the tapes come closer and in fig. b) they go apart"), as a movement of two parts of a system.

CONCLUSIONS AND IMPLICATIONS

The considerable number of pertinent answers to the questions, even in the starting activity, with pulled adhesive strips, suggests that the tasks are well- established for the pupils level. As regards the research questions, we argue that the reading of the behavior of systems shows a rather sharp distinction between the fourth and fifth classes. The fourth classes look substantially in terms of interaction, repulsion between the tapes, while in the fifth classes are limited mostly to describe the observed behavior of distancing. Moreover, in this case emerges a description that seems more attentive to the changed appearance of the single tape, which "leans", than to the relationship between the two tapes as an interacting system. The simplicity of the experiences has facilitated their reading, but not the process analysis. The majority of pupils in this group after examining later experiences noted the distancing one from the other of the interacting systems. This supports the need to propose a lot of experiences, varying conditions, to facilitate the identification of significant elements for the analysis of the phenomenology. The fact that the vast majority of pupils in fourth class of primary school read the experience in terms of interaction indicates that reasoning based on it can be carried out since this level of education; confirming it the majority of pupils in the fourth class still shows the forces when providing an interpretation of the experience. The reasoning in terms of interactions can be carried out from primary school level, with long-term thinking. The vast majority of students identified the pulling as the action that produces the new behavior of the system, but almost half of the students also indicates the approach, which makes visible but does not determine the interaction. Again, as confirmed by subsequent experiences of friction, providing many experiences helps to identify the role of the magnitudes involved. The explanation of the observed behavior is given by a good number of pupils, who resort to physical entities for the interpretation: this is mostly the outcome of considerations that involve multiple entities and mechanisms in which the interpretative magnitude plays an improper role: it is necessary to get used pupils to the strict reading of the macroscopic phenomenology to help them in acquiring awareness in the control of inferences. From data emerge that pupils often modify their previous idea and describe processes in more generalized way, less related to the single system/situation and to contingent aspects. Finally, changing the way of prepare the charged state, they tend to interpret the observed phenomena as result of a process of interaction between two sub-systems or almost they tend to consider all the two sub-system as a whole. Observing the same process in different ways pupils overcome a vision linked to local descriptive/contingent details, looking at the whole system and process as such. This conceptual steps is usually activated by the SPEA cycle. The habit to propose to the learners only one experience (usually regarding induction) is not enough to produce adequate learning outcomes. Observing that the class where in a first time emerged mechanisms of explanation has come to identify the presence of "something" in the systems as an element of explanation, in advance of the planned steps in the path, the search for interpretation by pupils should be encouraged. To get that the identified entities are used in relevant ways, groups of different experiences are needed, which lead to highlight further properties of charge (in particular its mobility), while consolidate and clarify the basic interpretative idea. In this way the interpretation process is facilitated and new meanings are produced.

SCIENTIFIC KNOWLEDGE AND LEARNING IN BIOLOGY AND GEOLOGY: BETWEEN PHENOMENON AND EVENT

Denise Orange Ravachol[1] *and Christian Orange*[2]
[1] CREN, EA 2661, Université de Nantes - IUFM des Pays de la Loire
[2] CREN, EA 2661, Université de Nantes - IUFM des Pays de la Loire

Abstract: In France, biology and geology are associated in a whole subject matter called Sciences de la Vie et de la Terre (SVT, Earth and Life Sciences). This association is justified by the double dimension of these sciences, as they are both functionalist (they study living systems and Earth functioning, respectively) and historical (they reconstruct the evolutionary history of living beings and the Earth's past) sciences. This double dimension induces didactical problems due to the fact that, on one hand, most of the questions to work on in SVT classes are hybrid (both functionalist and historical), and on the other hand because students use storytelling to solve historical questions. Which references could help to go beyond these difficulties? Our communication aims to build them by situating SVT between phenomena and events sciences. By considering two historical problems (the formation of a mountain range, and the origin of life on Earth), we perform a comparison analysis of the way events and phenomena are mobilized by researchers and students. We show that, due to a lack of experience in biology and geology, students involve "catastrophic" events and thus remain in a common thought. We notice that the French curricula give no clues to teachers to deal with this epistemological issue.

Keywords: biology, geology, event, phenomena, student

INTRODUCTION

In the French curricula, biology and geology are associated in a whole subject matter called *Sciences de la Vie et de la Terre* (SVT, Earth and Life Sciences). This association, which does not exist in all countries, was justified by their double dimension (Mayr, 1982 ; Gould, 1989) : biology and geology are both functionalist (they study living systems and Earth functioning, respectively) and historical (they reconstruct the evolutionary history of living beings and the Earth's past, respectively) sciences.

- For biology, Mayr emphasized that « *there is hardly any structure or function in an organism that can be fully understood unless it is studied against this historical background* » (1982, p. 69) ;
- For geology, Gould said that the trend of considering this science as "soft" or "merely descriptive" as opposed to "hard" and "rigorously experimental" science is because it requires the tools of history for explaining some natural phenomena (the Cretaceous exctinction, for example).

In this communication, we analyse the didactical consequences of this characteristic by considering the theoretical framework of *learning-through-problematization* that strongly links learning to problems'construction and admits that the scientific knowledge not only contains the solutions to these problems but also the reasons that make them necessary (assertoric knowledge vs apodictic knowledge).

RATIONALE

This double dimension leads to didactical issues because, on one hand, the problems to be treated in SVT classes are hybrid (functionalist and historical) and, on the other hand, students tend to make small stories (*storytelling*; Orange Ravachol, 2010).

- The seafloor spreading, for example, can be seen as a functionalist problem (the current functioning of a mid-ocean ridge) but also as a historical problem (reconstruction of an ocean history);
- Most of students reduces the seafloor spreading problem to plates drift stories. For scientists, the plates are in constant renewal; for students, they are as characters that can move away or get closer on the surface of the Earth, while keeping their integrity.

This communication, which takes place within the theoretical framework of *learning-through-problematization* (Fabre & Orange, 1997), tries to define the conditions that would allow to overcome these difficulties, from case studies.
In order to identify the conditions of an understanding and an assimilation by students of the double dimension of the SVT, we need to improve the epistemological structure of these disciplines.

What links biology and geology?

Due to their double dimension, functionalist and historical, biology and geology have a complex connection with time (Orange & Orange, 1995). To reconstruct the past, thus unique, living beings history or Earth history, these subject matters need to invoke contingency and to produce a time not entirely definite, and that provides singular events. Time becomes history by building events (Tintant, 1986).
However, in their functioning, biology and geology also show a tendency to move away from history and thus from historical events:

- When they explain by invariable laws in time and space how the Earth or living beings are functioning, they build a “void” time that gives no place to event.
- When they use the principle of actualism, they bring an historical dimension back to a functionalist dimension, so events are withdrawn in favour of phenomena.

Biology and geology therefore operate in paradoxical ways. To construct a reasoned history of Earth or living beings, they identify past events as current phenomena. By doing so, they appears like they are "killing" history. But it is to eventually better find it, because events become necessary when the projection on the present time is impossible.

What distinguishes geology from biology?

By using the principle of actualism, geology usually succeeds in bringing an historical dimension back to a functionalist dimension, thus changing events into phenomena. On the opposite, historical biology remains marked by the consideration of contingency and events, as it involves the history of mankind, which gives sense to events that appear crucial. We can use as examples some historical problems: the formation of the alpine range, the dinosaur extinction, the origin of life on Earth. Despite all these problems took place at different moments of Earth’s history, and thus have factual characteristics, they are not treated in the same way by the scientific community (Table 1).

Examples of historical problems	Treatment by present scientists.
Formation of the alpine range	- Treated as a phenomenon (an example of the formation of a mountain range), by using an elaborate form of the principle of actualism.
Dinosaur extinction	- Treated as a phenomenon (an example of biological crisis), by using both elementary and elaborate forms of the principle of actualism. - Treated as an event when it allows to explain the rise of Mammals during the Tertiary.
Origin of life	- Succession of events, at least during a part of the process (non robust reactions).

Table 1. Some problems in historical geology and their treatment by present scientists

So we can sum up on the next figure (Figure 1) how complex is the relation between phenomemon and event, both in biology and geology.

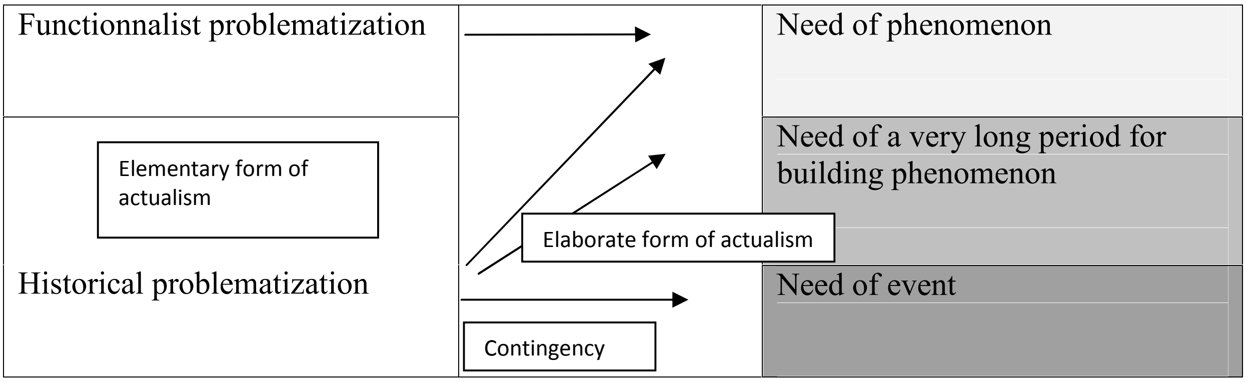

Figure 1. Functionalist and historical problematizations and phenomenon and event construction

Several kind of contingencies are not taken into account by scientists:

- The possibility that Alps could have not existed does not interest them; instead of considering this formation as an event, scientists consider it as a kind of orogenesis.
- On the opposite, the fact that the dinosaur extinction could have not happened is considered, probably because it conditions what happens afterwards, until the apparition of the human species (Stengers, 1997).

Biology and geology thus do not take into account phenomena and events the same way, which allows to anticipate didactical issues.

METHODS

Our studies deal with a comparative analysis of the way events and phenomena are mobilized during the *problematization* of two historical problems (the formation of a mountain range, and the origin of life), by researchers and students. For that, it is based on:
1) an epistemological analysis of the knowledge involved ;
2) interviews with specialized scientists ;

3) the explanatory and argumentative productions of students facing these problems (grades 11-12, 16-18 years-old) during individual works or semi-directive interviews.

From the point of view of using the principle of actualism

Geologists explain the formation of the Alps (figure 2) by using the principle of actualism :

- pillows lavas (“*laves en coussins*”) found in the mountains are pieces of an ancient ocean (analogy with the current ocean expansion)
- the presence of relief is linked to current compressive processes, over a very long period of time.

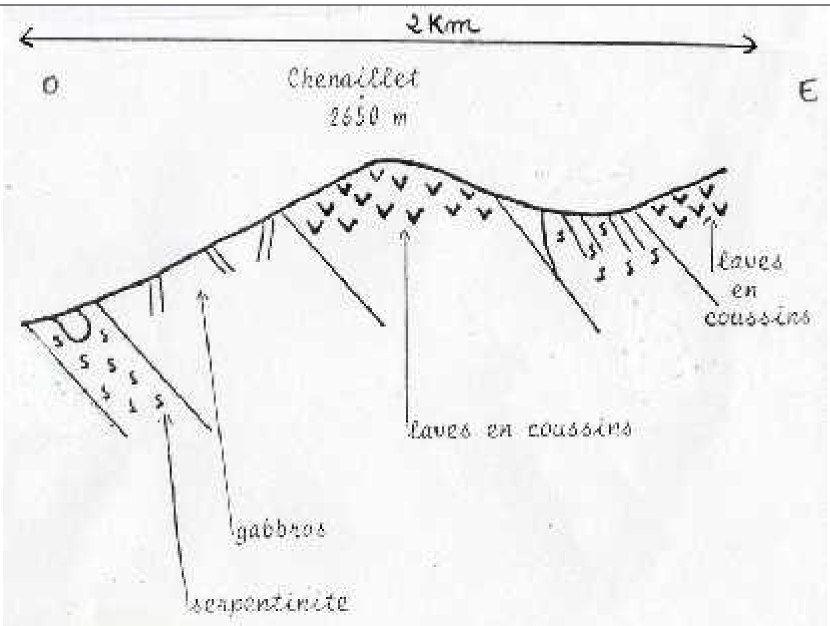

Figure 2. Cross section through the Alps (Mount Chenaillet)

Do students refer to current processes? Do they build the necessity of a long period of time producing the orogenesis ?

From the point of view of a retrospective reconstruction of the event

Geologists explain the origin of life by a succession of events whose occurrence was very uncertain *a priori*. They establish these events with a retrodiction approach (figure 3).

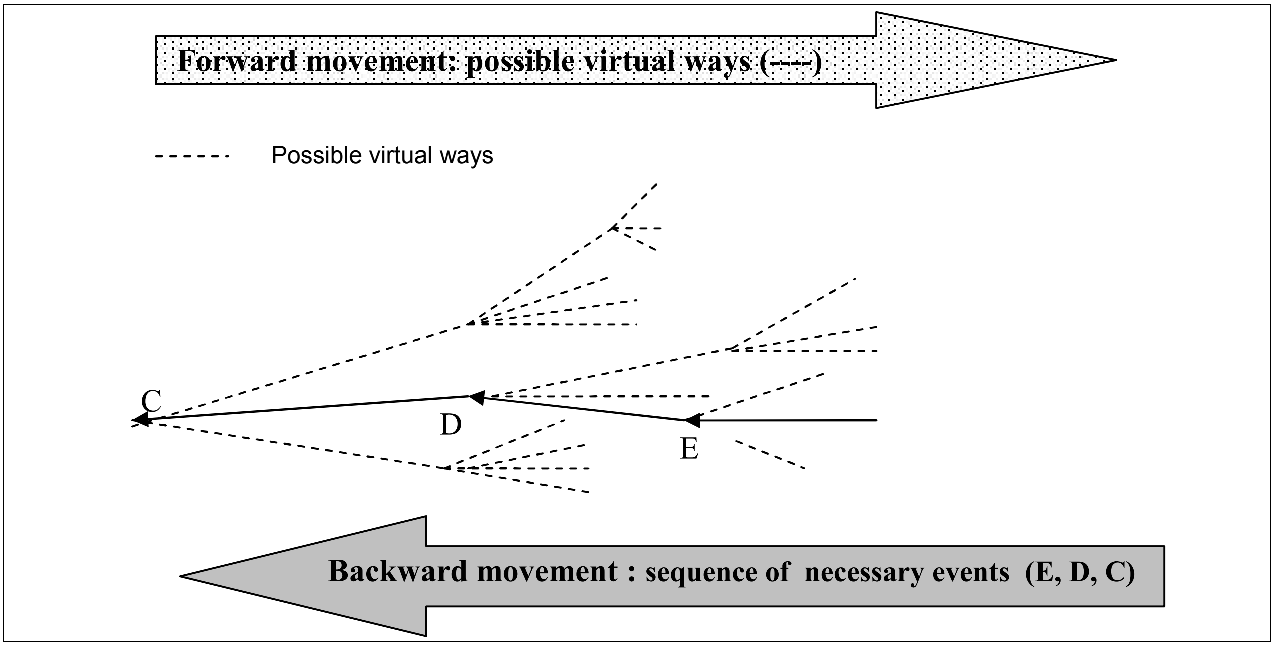

Figure 3. Contingency, virtual possibilities and event needs

The origin of life becomes a necessary event when we consider the history of life backwards. Do students consider the apparition of life on Earth as a common phenomenon or as a singular event in space and time? If they consider it as an event, how do they build it?

RESULTS: STUDENTS FACING EVENTS AND PHENOMENA

In their explanation of the formation of the Alps (figure 2), students situate pillows lavas on a seafloor and they imagine movements explaining their present location. But these movements are not controlled and have no constraints (figure 4). These are *ad hoc* events; everything is possible within time and space. Instead of looking on the orogenesis as a phenomenon and constructing the necessity of a very long period to obtain it, they consider it as a catastrophic event.

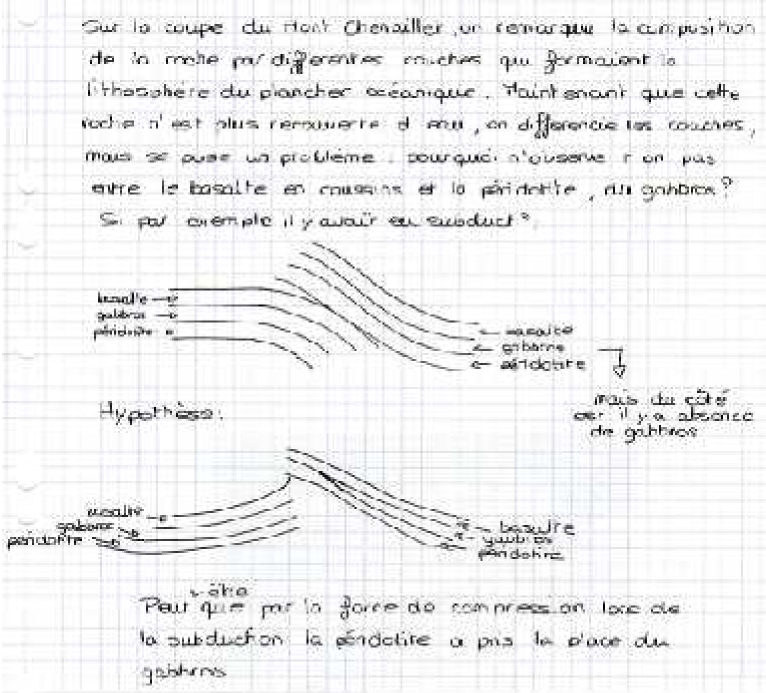

Figure 4. A student's explanation of a part of the Alps (Mount Chenaillet)

Most of students consider the origin of life on Earth as a common event: when condition where favourable (suitable temperature, presence of liquid water), living beings appeared. Some of them imagine the apparition of life by starting from the present time. As scientists, they take the history backwards (example: the sexual reproduction where it is impossible to have children without parents ; obtaining plants from seeds placed in favourable conditions) and have difficulties to construct the necessity of an origin. Students are thus able of reasoning by taking the history backwards or forwards. But by going backwards, they do not find an origin; and by going forwards, they make simple forms that evolve as they wish, without constraints.

CONCLUSIONS AND IMPLICATIONS

The usual reasoning way of students does not lead them to understand the distinction between events and phenomena. Students frequently use events in a short story. This tendency is already used in physics (Viennot, 1996). If they are powerless, it is mainly because they are not able to control their story and to construct the necessity of each event, due to a lack of theoretical and empirical experience in biology and geology. The use of the events by students is thus in a catastrophic or stopgap way. Behind this lack of distinction between event and phenomenon, we show that they miss a fundamental characteristic of historical biology and geology and the essential difference between them.

Abstract: In this paper a comparison between Greek and Serbian teachers is made, in order to investigate acceptance and understanding of evolution theory. It is a report of broader study, whose aim is to highlight the important factors of the conceptual ecology related to evolution theory. Particularly, in this paper we report levels of acceptance and knowledge among teachers and especially science and biology teachers in both countries. A questionnaire was constructed and was applied to a total of 318 Greek and 341 Serbian teachers. In our findings, we mention low levels of understanding of ET, even in biology teachers, in both countries. We also report moderate levels of ET acceptance, with the exception of biology teacher's high acceptance, in both countries. Our results show that Greek teachers performed better on understanding evolution theory in comparison with the group of Serbian teachers, but there is no significant difference between the Greek and Serbian teachers of the acceptance of the evolution theory, as a whole but there are significant differences between various teachers' groups. Significant, but no strong, correlations between acceptance and understanding evolution are recorded; this supports our claim that understanding is a factor of evolution theory's conceptual ecology, but not the more significant one. Findings indicate the necessity to enhance the evolution teaching in both educational systems. Modern biology teaching process for all the levels of education and teachers training, should involve the adequate didactic transformation of evolution content.

Keywords: evolution theory, conceptual ecology, acceptance, knowledge, teachers

RATIONALE, AIM AND OBJECTIVES OF THE STUDY

Evolution theory (ET) is broadly accepted as the central theory of biology, however, despite this, in many countries of the world there exist controversies and the polls show that the acceptance of ET across adult population is restricted (Miller, Scott, & Okamato, 2006). Public understanding of evolution is considered woefully lacking by most researchers and educators. Evolution is considered as concept - threshold that needs to be passed before someone can develop his/her understanding (Kinchin, 2010) of a broader perspective of natural phenomena and of the nature of science. Despite this, educational research has shown that the ET teaching in various parts of the world has not the expected results. Moreover the acceptance of the ET is restricted and the knowledge is limited and controversial among school science students and teachers (Demastes, Good & Peebles, 1995; Deniz, Donnelly & Yilmaz, 2008; Peker, Comert, & Kence, 2009; Nehm, Kim & Sheppard, 2009). High percentages of science teachers reject ET and support the teaching of antievolutionary ideas in schools (Nehm & Schonfeld, 2007). Thus evolution remains a problematic subject for many science teachers.

As teaching and learning evolution in a biology classroom is more than a cognitive-only process and affective factors are evoked more strongly when learning a topic such as evolution, we adopt the claim that conceptual ecologies of both teachers and students influence the process of teaching and learning (Deniz, Donnelly & Yilmaz, 2008). Studying, therefore, the acceptance of ET as a part of the conceptual ecology (Posner, Strike, Hewson, & Gertzog, 1982; Strike & Posner, 1992) for biological evolution is more promising than studying the acceptance of evolutionary theory in isolation, due to the fact that, in this theoretical framework, the fundamental importance of intuition, emotion, motives and social factors was acknowledged (Strike & Posner, 1992). Factors that are together called learner's "conceptual ecology" of evolution theory are documented in previous research (Demastes, Good & Peebles, 1995; Deniz, Donnelly & Yilmaz, 2008). They describe that the conceptual ecology for biological evolution contains the following: prior conceptions related to evolution or understanding of ET; scientific orientation (degree to which the learner organizes his/her life around scientific activities); view of the nature of science; view of the biological world in competitive and causal terms as opposed to aesthetic terms; religious orientation, reasoning level; perceptions of the impact of the ET; epistemological beliefs, and thinking dispositions. Deniz, Donnelly & Yilmaz, (2008) added parents' educational level as a factor related to ET acceptance.

There is a need to clarify the terms belief and acceptance, at least the meaning we accept and the way we use them. We do not use the term "belief" as it is considered to be a subjective way of knowing, and it can potentially blur the line between scientific knowledge and religious belief (Sinatra, Southerland, McConaughy & Demastes, 2003). We choose to use the term "acceptance" which is equated with attitude (Ingram & Nelson 2006) and is the most basic attitude toward evolutionary principles and conclusions" (Brem, Ranney, & Schindel, 2003).

According to Smith's review (2010) science education research has taken an interest in the possible relationships among accepting and understanding evolution and particularly if the constructs are correlated or not. In biological domains other than ET, research supports the generalization that knowledge and belief are loosely associated constructs. In the case of ET, in the majority of the studies was found that knowledge and belief are weakly associated constructs though (Smith, 2010). Notably, in some studies was found that knowledge of ET was significantly related to the acceptance of ET.

Build on previous research, this comparative study focused on the factors which make out the conceptual ecology of the evolution theory of Greek and Serbian teachers. From the aforementioned factors we choose to investigate acceptance and understanding –presented in this study in a comparative way - in addition to thinking dispositions, perceptions about the nature of science and religiosity. The following research questions are at issue in this study: (1) to what extent do Greek and Serbian teachers accept and understand the ET? (2) What is the relationship between acceptance and understanding of the ET? Are there differences between Greek and Serbian teachers in this case? (3) What are the differences in acceptance and understanding between teachers of different scientific background in Greece and Serbia? We choose to conduct a comparative study in two ways – between teachers differing in subject matter knowledge and coming from two different countries for two reasons: (1) According to Nehm, Kim and Sheppard (2009), studying biology teachers is a direct and obvious approach for exploring putative associations among subject matter knowledge and belief (and/or advocacy). Broadening sampling strategies to include comparable cohorts of non-biology teachers should be informative. (2) In order to have a better understanding of the conceptual ecology in general, and of the acceptance – knowledge relationship in particular, we choose to develop the same research design in two countries with the same religious orientation. This choice was guided by the findings of previous research that religiosity is an important component of ET's conceptual ecology in Greek cultural frame (author1 & author4, 2011). We hypothesized that there should be differences among people with the same religious orientation but from different cultures, because different socio-cultural backgrounds, religious histories or the traditions of these people.

METHOD

The participants of the study were 318 teachers from Greece and 341 teachers from Serbia. The Greek participants were 78 teachers of Early Childhood Education, 70 Primary Teachers and 152 Secondary Science Teachers (78 Biologists, 24 Physicists, 42 Chemists, 6 Geologists and 2 teachers with other science studies). In this group, women were 61.7% or the sample and the mean teaching experience was 14.9 years (min=1, max=35, SD=9.42). The Serbian participants were 53 teachers of Early Childhood Education, 70 Primary Teachers and 218 Secondary Science Teachers, women were 77,4%of the participants and the mean teaching experience of 16.13 years (min=1, max=38, SD=10.04).

Data Collection was done by the use of the same questionnaire in both countries. The Serbian survey was conducted by personal administration of the research tool to the participants, while the Greek survey was partly web-based and partly personally administrated. The questionnaire was consisted by the next measurements:

Demographics: Teachers responded to five demographic questions which were focusing on gender, age, studies and teaching experience.

Knowledge measure: Teachers' understanding and knowledge of the ET was estimated by means of a scale (adopted from Rutledge & Warden 2000 and adapted for the needs of our study) with 13 questions consisting of two sub-scales. One subscale of 8 questions that had to do with the understanding of very basic principles of the evolutionary theory and was of a Correct-False-Do not know type and the other of 5 multiple choice questions, was concerned understanding of procedures and practices on the evolution of populations. Scoring was performed through a scaling where the correct response to a statement received a score of 1, whereas wrong responses received a score of 0 (Possible total scores min=0, max=13).

Acceptance: To assess students' acceptance of evolutionary theory, we used the MATE scale (*Measure of Acceptance of the Theory of Evolution*), developed by Rutledge and Warden (2000). MATE consists of twenty Likert's -scaled items containing statements that addressed the fundamental concepts of evolutionary theory and the nature of science (Rutledge and Sadler 2007). To score the MATE we follow Rutledge and Warden (1999) procedure, that is: a) to account for positively and negatively phrased items, the scaling of responses were appropriately reversed so that responses indicative of a high acceptance of evolutionary theory received a score of 5, while answers indicative of a low acceptance receive a score of 1. b) An individual's score on the MATE was equal to the sum of the scaled responses of all 20 items.

Data and results processing was performed by applying the basic statistical methods/table-descriptive statistics (means, standard deviations, and maximum and minimum of surveys' responses) with PASW Statistics 18.

FINDINGS and DISCUSSION

Table 1: Acceptance Evolution Theory in Greek and Serbian Teachers

	Greece			Serbia		
	M	**SD**	**SEM**	**M**	**SD**	**SEM**
Acceptance of evolution theory - MATE scale						
Total score *(possible min=20, max=100)*	**76.24**	9.952	0.594	**76.18**	9.821	0.532
Preschool Education Teachers	**72.73**	9.019	1.127	**69,68**	7.450	1.023
Primary Teachers	**75.28**	7.929	0.991	**73.99**	10.214	1.221

Chemists	**7.64**	2.017	0.331	**6.13**	1.638	0.194

In the tables 1 and 2, we present the mean scores, standard deviations and standard errors of mean, in acceptance and understanding ET scores of all the teachers participated in our study in Greece and in Serbia. We also present the scores, standard deviations and standard errors of mean, both in acceptance and understanding ET, recorded in teachers with different subject matter knowledge i.e. Biologists, Physicists and Chemists.

a) **Acceptance:** Following the categorization developed by Rutledge and Sandler (2007), acceptance levels are moderate in total groups (mean score: 76.24 for Greeks and 76.18 for Serbians), but science teachers of two countries score in high category (mean score: 78.38 for Greeks and 78.46 for Serbians). This high score in secondary teachers is due to Biologists' high score in both countries, also to Greek Physicists' and Serbian Chemists' high level scores (table 1).

Secondary science teachers, in both countries, performed better than their Primary and Preschool Education counterparts. Some of these differences are significant (Greek: Secondary – Preschool Education teachers, mean difference= 5.63, sig<0.01. Serbian: Primary – Preschool Education teachers, mean difference = 4.31, sig<0.05. Secondary – Primary School teachers, mean difference = 4.48, sig<0.01. Secondary – Preschool Education teachers, mean difference = 8.78, sig<0.01.

Biology teachers performed better (mean score: 80.25 for Greek and 84.56 for Serbian) in comparison with other science teacher in both countries. Significant differences in acceptance score are observed: in Greek secondary science teachers between Biologists -

Chemists, mean difference = 6.09, sig<0.05. In Serbian teachers significant differences are observed between Biologists – Chemists, mean difference = 5.75, sig<0.01, Biologists – Physicists, mean difference =12.64, sig<0.01.

Greek teachers, totally, score higher in comparison with Serbian teachers, but this difference is not significant. Also, there is a difference between Greek and Serbian biology teachers in favor of Serbian, but this difference is not significant. Significant differences in acceptance scores are observed between: Greek – Serbian Biologists, mean difference -4.32, sig<0.01, Greek – Serbian Physicists, mean difference 5.21, sig<0.01.

b) **Understanding:** In both countries understanding levels are very low (mean score: 7.14 for Greek and 5.82 for Serbian teachers) (Table 2).

Secondary science teachers, in both countries, performed better in understanding score than their Primary and Preschool Education counterparts (Table 2). Some of these differences are significant, particularly: in Greeks Secondary – Preschool Education teachers, mean difference=1.91, sig<0.01 and Secondary – Primary Education teachers, mean difference=1.56, sig<0.01. In Serbians, Secondary – Preschool Education teachers, mean difference=1.91, sig<0.01, Secondary – Primary Education teachers, mean difference=1.01, sig<0.01 and Primary – Preschool Education teachers, mean difference=0.90, sig<0.05.

Biologists' score in understanding ET is slightly better than the other teachers groups, but their score levels are still low. Specifically, there are not significant differences between Greek science teachers with various scientific backgrounds. In Serbian teachers, there are significant differences in understanding score between: Biologists – Physicists, mean difference =1.65, sig<0.01 and Biologists - Chemists, mean difference =1.12, sig<0.01.

Higher scores were observed by groups of Greek teachers in comparison with groups of Serbian teachers. The majority of these differences are significant, specifically: Greek – Serbian Secondary teachers: Mean difference 1,619, sig< 0.01, Greek – Serbian Primary teachers: Mean difference 1.08, sig<0.01, Greek – Serbian Kindergarten teachers: Mean difference 1.62, sig<0.01. Also significant differences are observed between: Greek – Serbian Physicists: Mean difference 1.66, sig<0.01 and Greek – Serbian Chemists: Mean difference=1.52, sig<0.01

c) **Correlations:** There are positive significant correlations between understanding and acceptance of evolution theory, both in Greek (r=0.248, p<0.01) and Serbian groups of teachers (r=0.353, p<0.01).

In comparison with other studies which investigate acceptance of ET (measured with MATE scale), results of Greek and Serbian teachers are very similar to the Oregon biology teachers who achieved 85.90 for mean score of acceptance (Trani, 2004). Turkey preservice biology teachers achieved only 50.95 for mean score of acceptance (Deniz, Donnelly, & Yilmaz, 2008), and Indiana biology teachers achieved 77.59 for mean score of acceptance (Routledge & Warden, 2000). These are low achievements in comparison with results of Greek and Serbian teachers.

Taking into account the other categories of teachers, secondary and primary school teachers from New Zealand achieved 84.55 for mean score of acceptance (Campbell & Cook, 2003), which is very similar to the results of Greek and Serbian biology teachers. Non biology majors from United States achieved only 55.87 for mean score (Rutlege & Sadler, 2007).

Our results indicate that there is a positive correlation between acceptance and understanding ET. Also, there are some other studies, which have shown positive correlations between acceptance and understanding (Rutledge & Warden, 2000). But, there are some others which have found no statistical relationship between these variables (Demastes, Good & Peebles, 1995; Brem, Ranney & Schindel, 2003; Sinatra, Southerland, McConaughy & Demastes, 2003).

CONCLUSIONS AND IMPLICATIONS

Based on results, presented for the Greek and Serbian groups of teachers, it can be concluded that there is no statistically significant difference between the groups of Greeks and Serbian (as a whole) in acceptance of evolution theory.

Also, we can see that there are significant differences (in total score) between the Greek and Serbian teachers for understanding ET. Greek teachers score is higher than their Serbian colleagues both in acceptance (no significant) and in understanding (significant).

We maintain that differences in understanding ET between Serbian and Greek teachers exist due to differences between the two educational systems.

Greek and Serbian biology teachers have higher scores for understanding and acceptance in comparison with the other science teachers. It can be explained by the existing of evolution teaching content on their studies.

Generally speaking, it seems that understanding goes with acceptance, that means cohorts with higher understanding score shows also and a higher score of acceptance, but there are two exceptions: Serbian Biologists and Chemists. Greek teachers score higher than their Serbian colleagues both in acceptance and in understanding, with two exceptions: Serbian Biologists and Chemists. In this case, our initial hypothesis that there should be differences among people with the same religious orientation but from different cultures seems to be true.

There are positive correlations between knowledge and acceptance for Greek and Serbian groups of teachers. Weak and moderate, even significant, correlations between acceptance and understanding indicate the need to investigate other factors of conceptual ecology of ET. Finally, these levels of understanding ET represent a challenge that educational systems in both countries need to address in order to provide legitimate biological education.

There is a need to change and transform didactically ET content, in both countries, especially in textbooks and courses. Teachers in both countries would benefit from more training in evolutionary science and also in methods of transforming and teaching ET content. There is a need of training in evolution for Primary and Preschool Education Teachers too. Primary teachers in both countries are teaching about living organisms and their adaptations and evolutionary perspective is a necessary condition for effective teaching. Finally evolutionary perspective is very possible to influence the kind of the narratives that kindergarten teachers adopt about living organisms and their history in the Earth.

Abstract: Several studies have showed that children initially discriminate living things and nonliving things according to perceptual characteristics. They also make mistakes in categorizing living and nonliving things according to the corresponding ontological categories and in using the biological functions of organisms as systematic criteria to discriminate them.
This paper describes the results of an empirical study focused on the biological conceptions held by children aged from 4 to 6 years. It also describes the conceptual change as a result of instruction based on constructivist teaching. Our findings showed that younger children correctly attributed the ontological categories animals and nonliving things, but they did not automatically assign the biological properties to the item classified as living. Moreover, after the instruction we observed a significant improvement in sorting animals and plants as living and in the attribution of biological properties to the living things.

Keywords: Biological conceptions, conceptual change, active learning, primary school, preschool.

INTRODUCTION

Children's ability to distinguish between living and nonliving things has been extensively studied by psychologists and educational researchers (Hatano & Inagaki, 1997; Caravita & Falchetti, 2005). Authors emphasize that during the school age, children have not still developed their biological conceptions according to the scientific accepted theories and that their conceptions about natural phenomena may differ from those of scientists (Carey, 1985). For an adult, considering an entity as alive also means attributing to it some biological properties which are typical of the living things (such as growth, eating, breathing), while a child may not use biological properties as a criterion to distinguish living and nonliving things, as some authors suggested (Gutheil *et al*., 1998; Inagaki & Hatano, 2002). Some authors hypothesized that children's difficulty in discriminating living and nonliving things could arise from mistakes made by children when attributing concepts to one of the three ontological categories – matter, processes and mental states – among which they make an early classification of the reality (Chi *et al*., 1994). Many studies which focused on children's ability in discriminating between living (animals and plants) and nonliving things, showed that, from a developmental perspective, children consider plants as a sub-category of the living domain later than animals (Inagaki & Hatano, 1996; Labrell & Charlieux, 2009; Nguyen & Gelman, 2002; Richards & Siegler, 1984). From an educational point of view many researchers emphasized that instructional activities based on an active and cooperative learning were effective in promoting an early understanding of biological concepts in children (Nigris, 2007; Niemi, 1997; 2002).
From a methodological perspective, in the cited studies, animals, plants and inanimate objects were rarely involved at the same time. Moreover, children are generally asked with questions

which require a yes/no answer (Carey, 1985) or with open-ended questions sometimes following an explanation of a given property (Inagaki & Hatano, 1996). In our opinion, for a young child, answering a question implies not only to recall the proper information, but also to be able to construct a verbal response: given the young age of the interviewed children, it is likely that their verbal ability is still immature and that could therefore affect their responses. Besides, some authors stressed out that some questions may appear ambiguous to the child (Hatano & Inagaki, 1996). We thus decide to use a sorting task with pictures for collecting data which are not influenced by young children's poor ability in speaking. Therefore, aims of the present study are: a) to describe the understanding of children between 4 to 6 years concerning the categories of living, nonliving, animal, plant and their biological properties; b) to assess the conceptual change which emerged further to an instructional program.

METHOD

The participants were 68 children: 37 preschoolers (17 girls, 20 boys, mean age 5.3 years) and 31 first-graders (16 girls, 15 boys, mean age 6.7), coming from five different classes of two public schools located in Rome (Italy). Three age levels were considered: 4-year-olds (5 girls, 8 boys); 5 year-olds (10 girls, 11 boys); 6-year-olds (18 girls, 16 boys). The entire sample was divided in two subgroups: the experimental group, constituted by 24 preschoolers (12 boys, 12 girls, mean age 5.3) and 17 first-graders (10 boys, 7 girls, mean age 6.6), and the control group constituted by 13 preschoolers (8 boys, 5 girls, mean age 5.3) and 14 first-graders (5 boys, 9 girls, mean age 6.8). To assess children categorization of living things and biological properties attribution, we administrated our sample with a task using 9 photo-cards, showed in Figure 1. They represented: a) animals: a dog, a fly, a starfish; b) plants: a common European species of daisy (*Bellis perennis*), an oak tree (*Querqus sp*), grass; c) nonliving things: a stone, a bike, a teddy bear. During the task, children were asked to sort the cards in living, nonliving things, animal, plant, and to attribute them seven biological properties: birth, growth, eating, breathing, reproducing, falling ill, and death.

Figure 1. Materials of the sorting task.

Children responses were coded as correct (0) or incorrect (1). The dependent variables used were the scores of the correct sorting of animals, plants and things as living (each one with a

0-3 range), a score for animals and plants correct categorization as living (range 0-6), a score for the correct attribution of biological properties to animals and plants (score 0-6) and a global score for the correct attribution of biological properties (range 0-9).
With respect to the first aim, we conducted descriptive analysis considering the whole sample grouped by age levels. We also conducted two ANOVAs: one with Age (3) and Category (3) as factors; the other with Age (3) and Property (7) as factors. With respect to the second aim, we analyzed the effectiveness of instruction by comparing children's knowledge before and after the instructional program with that of the control group. We therefore conducted ANOVA analyses with Group (experimental vs. control) and Time (pre-test vs. post-test) as factors.

Instructional program

Teaching was displayed for the experimental group only, while the control group did not receive any instruction on the same contents. The instructional program lasted 8 weeks, for a total of 52 hours. Pupils worked in a learning environment in which they could found living organisms so that they had the possibility to improve experimental observations. The training, as showed in Table 1, was characterized by direct observations on living plants and animals, the use of drawing as a tool to describe the natural objects, and was based on cooperative learning activities (for example, group discussions, group hypothesis testing).

Table 1. Characteristics of the instructional program

Characteristics	Unit 1: Plants	Unit 2: Animals
Aims	To distinguish living and nonliving things To classify plants and animal To attribute biological properties to living things	
Contents of learning	Living and nonliving things Seven biological properties: birth, growth, eating, breathing, falling ill, reproducing, dying	
Investigated objects	Flower, Pine Seed, Grass, Bean, Lentil	Ant, Snail, Earthworm
Lab activities	Collecting samples, Observation, Description, Sorting	
	Seeding under different environmental conditions. Discussion	Breeding Discussion
Educational methodology	Constructivist Approach Scientific Method	
Educational strategies	Personal and group investigation Working in natural environment Naturalistic drawing	
Evaluations	Tasks	

RESULTS

With respect to the first aim, we analyzed children sorting of animals, plants and nonliving things and how they correctly attributed to them the biological properties. Considering the whole sample, a higher percentage of children sorted animals as living than plants (respectively, 84% against 59%). Nonliving things were correctly sorted by the majority of the children (78%). ANOVA analysis showed an Age x Category interaction [$F(4, 130) = 2.473$, $p = .048$; see Figure 2] and post-hoc analyses revealed that: 5- and 6-year-olds scored significantly better in sorting animals than 4-year-olds; 6-year-olds produced more correct sorting for nonliving than 4- and 5-year-olds.

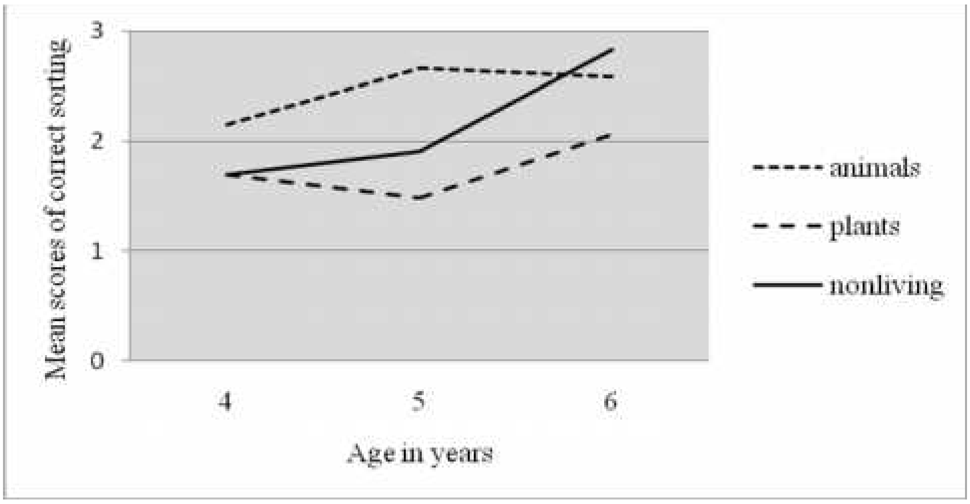

Figure 2. Children's correct sorting of animals, plants and nonliving things at 4, 5 and 6 years old.

The same analyses also showed that 5-year-olds scored significantly better in sorting animals than plants and nonliving, and that 6-year-olds produced more correct sorting for animals and nonliving than for plants. Thus, children's conceptualization of living and nonliving increases with age for animals and nonliving but not for plants. Concerning the biological properties, even if 75% of children correctly did not attribute them to nonliving things, only 27% of them assigned such properties to plants and 25% to animals. We found a significant Age x Property interaction [$F(12, 390) = 2.881$, $p = .001$]. Post-hoc analyses revealed that the attribution of birth, reproducing and dying properties significantly increase with age (see Figure 3).

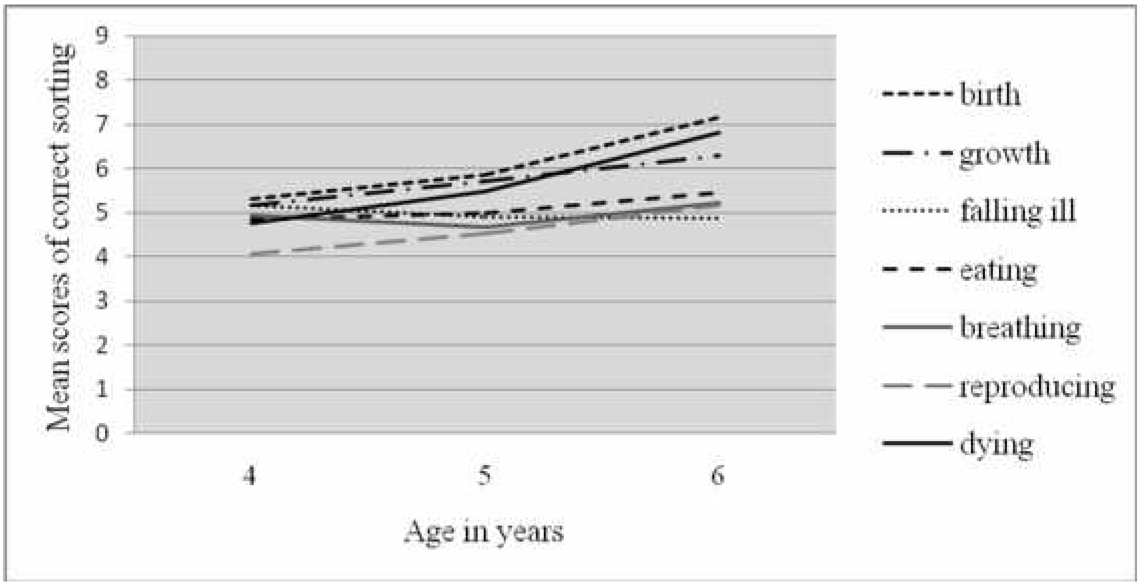

Figure 3. Children's correct attribution of biological properties at 4, 5 and 6 years old.

Moreover, 4-year-olds did not show any difference in properties attribution, whereas 6-year-olds scored significantly better in attributing birth, dying, and growth than the other properties.
With respect to the second aim, to assess the effect of instruction we conducted, separately for preschool and first-grade children, analyses of variance calculated on the score for the correct categorization of animals and plants as living and for properties attribution to them considering as factors Groups (experimental vs. control) and Time of assessment (pre-test vs. post-test). Only significant interactions were considered, as they showed a teaching effect in experimental group. We did not considered the simple effects of Group and Time. As shown in Table 2, the correct sorting of animals and plants as living things increased significantly after the instructional program both for preschoolers and for first-graders. After the instruction, first-grade children also improved in correctly attributing all the biological properties to animals and plants, while preschool children only improved in correctly attributing the breathing and dying properties. A tendency was also observed after the instructional program in preschoolers' attribution of birth and eating properties.

Table 2. Anovas results for the Group x Time interaction

Category and properties correct attribution	Children group: Preschool	Children group: First-grade
Living	$F = 6.338$, $p = .017$	$F = 12.161$, $p = .002$
Birth	$F = 3.801$, $p = .059$	$F = 6.898$, $p = .014$
Growth	$F = .042$, $p = .838$	$F = 9.920$, $p = .004$
Falling ill	$F = 3.701$, $p = .063$	$F = 10.642$, $p = .003$
Eating	$F = 3.815$, $p = .059$	$F = 24.802$, $p < .001$
Breathing	$F = 6.792$, $p = .013$	$F = 24.109$, $p < .001$
Reproducing	$F = 3.310$, $p = .077$	$F = 7.690$, $p = .010$
Dying	$F = 13.097$, $p = .001$	$F = 5.365$, $p = .028$

DISCUSSION AND CONCLUSION

As we noted in the introduction, studies which focused on children's understanding about living things often analyzed separately animals, plants and inanimate objects, or compared living things using inanimate objects as distracters. Our research is one of the first analyzing at the same time children's understanding about the two sub-categories of living (plants and animals) and the nonliving category in children between 4 and 6 years of age. Moreover, we also analyze if they correctly attributed the biological properties.
Our results show that children's categorization of living things increase with age, with less difficulties to sort animals than plants, as previously shown (Richards & Siegler, 1984; Inagaki & Hatano, 1996; Nguyen & Gelman, 2002; Labrell & Charlieux, 2009).
Children of our sample were not able to attribute biological properties to all object classified as living. An explanation could be the different criteria to discriminate between animate and inanimate objects that children use, as Gutheil (1998) and Inagaki and Hatano (2002) suggested. Only the ability to attribute the birth, reproducing and dying properties significantly increases with age. Children improved in generalizing to several examples properties for which they have little or no direct experience, like birth, reproducing and death. One possible explanation of these results could be that children early understand those properties which are often objects of explanations from adults. In the family, but also at school, children receive explanations and listen narratives about birth, reproducing and death

which could help them to understand such processes earlier than of which they have more experience and that are less objects of adults explanations (such as breathing, eating, etc.). It is thus therefore possible to argue that children's knowledge, particularly for some biological properties and processes, do not only arise from personal experience, but also by cultural transmission.
After the instructional program, only first-grade children appeared to clearly differentiate living and nonliving things in terms of biological properties, since they assigned all the investigated biological properties to all the items sorted as living. Our results therefore suggest that after instruction, preschoolers improve in categorizing animals and plants as living, but it is only by age six that children appear to attribute the biological properties to all the living things. It means that the planned instructional program was effective in driving children's understanding to higher levels, but we have to verify the possibility to modify the program in order to be more effective for younger children.
In this research we used a task which did not require children to verbally answer a question but to choose from a set of images. The conceptions we found using this task were similar to those already described in literature. Moreover our non-verbal task was capable of capturing changes in the development of conceptions across ages, and to assess the conceptual change after the instruction. From an educational perspective, it seem also relevant to detect children's understanding before and after the instruction using structured tools, in order both to adapt the instructional intervention to conceptions really held by the children, and to assess the effectiveness of teaching.

CHINESE AND AUSTRALIAN CHILDREN'S UNDERSTANDING OF THE EARTH: A CROSS CULTURAL STUDY OF CONCEPTUAL DEVELOPMENT

TAO Ying, OLIVER Mary, VENVILLE Grady

Abstract: The purpose of this study was to explore Chinese and Australian primary children's conceptual understandings of the Earth. Participants were Year 3 and Year 6 children from three schools in Hunan Province, central south China (*n*=275) and Year 3 and Year 6 children from three schools in Western Australia (*n*=225). The children's general understandings were assessed by a science quiz developed from the past TIMSS science. In-depth interviews were carried out with a total 38 Chinese children and 36 Australian children to further explore their conceptual understandings of the Earth's shape, gravity, day/night cycle and seasons. The results showed that, regardless of different cultures, children from the same age group constructed similar concepts about the Earth. The Year 3 children tended to demonstrate intuitive conceptions of a round and flat Earth. The Year 6 children were more likely to demonstrate consistent understandings of a spherical Earth. Universality and cultural mediation in children's understanding of the Earth are discussed and a model of conceptual development is proposed.

HOW 16 YEARS OLD STUDENTS DEAL WITH ELECTRICITY CONCEPTS IN INQUIRY SITUATION

Claire Wajeman[1] *and Philippe Michel*[1]
[1] MeTAH/LIG, University of Grenoble, France.

Abstract: This paper reports a case study where a small group of 16 years old students is engaged in a productive and collaborative process through a SCY mission. This group designs and performs experiments on electricity, processes data, makes calculations, interprets the results and produces documents. From screen and audio records analysis, we look for what these students do with electricity concepts. Occurrences of concepts are coded to specify their characteristics and context of usage. We observe that the students very often encounter and mobilise the electricity concepts all along their work. This is partly due to recurrent difficulties. A comparison of the way students and teachers name concepts shows that the semiotic form of concepts' occurrences is an indicator of the students' mastery of the concepts. Most of the students' difficulties concentrate on physical quantities units and it leads the students to debate about the meaning of units and of the related physical quantities, and about the mathematical relation between concepts. These students also had problems using the web freely to search information. The role of teachers looks fundamental in this case: they guide the students to step out dead ends and to stay in a productive path, and they validate the students' work to support them to go on.

Keywords: Inquiry learning, Conceptual knowledge, Electricity, Web information search, Semiotic form

INTRODUCTION

In the SCY (Science Created by You) project (de Jong et al, 2010), the students are engaged in missions about socio-scientific topics, where they have to build objects (named ELOs, Emerging Learning Objects) following an inquiry and collaborative scenario. To create these objects, the students have to collect and organize information, design and perform experiments, process data, make interpretation, communicate their results and conclusions. One main assumption is that students' engagement in such active processes favours the acquisition of knowledge and skills. These pedagogical approaches can be efficient for developing social skills and scientific knowledge. Such pedagogical situations are not easy to build and organise (Puntambekar & Kolodner, 2005). In particular, careful scaffolding and guidance are often necessary (for a review see Hofstein & Lunetta, 2003).

RATIONALE

We are interested in how students encounter conceptual knowledge when they are engaged in the inquiry process of a SCY mission. We look for what students do with scientific concepts, for their needs and difficulties, and for the conditions that have an effect on the students' use of concepts. We do not want to test if students do learn concepts, but we seek for cognitive activities and for obstacles that may contribute to or hinder learning processes.

The SCY mission is to design a CO_2-friendly house, a family house with a carbon footprint as small as possible. The students work in groups of three, called design groups. The pedagogical scenario of the mission is organized in a jigsaw pedagogical approach where the students change roles and switch between their design group and an experts group: each student of a design group becomes a member of an experts group. An experts group has an expertise role in a specific domain (energy expert, thermal expert, domestic use expert) and has to explore the domain on a defined topic and make a report to the design groups.

As experts, a group of students has to deal with scientific concepts through a complete scientific process: setting questions, designing and conducting experiments, processing data, making interpretations and conclusion, reporting their work both in a written and oral form to their design group workmates. We present here a case study for a group of students working on electricity questions (domestic use experts). These students choose to evaluate the energy consumption of a TV with or without sleep mode; for this purpose, they have to measure power in order to calculate the energy using E= P*t law, and then compare values. These electricity concepts have been taught at a lower class level. We observe that these students are familiar with these concepts without mastering them.

DATA

The data are collected during the first trials of this SCY mission, with French students of 16 years old. The students work in experts' groups of 3 for about 5 hours on their own topics. Screen recorded data of students' activities on the computer, audio records, students' productions (ELOs) are collected.

METHOD

The screen/audio records are synchronised and then coded with a video coding software. A set of coding variables is used to characterise the occurrences of concepts used by the students according to our research questions. The records are coded separately by two researchers and the differences of coding are compared to reach an agreement.

We want to trace the way students use electricity concepts. By concepts we mean essentially the physical quantities. This is appropriate regarding the tasks that these students are performing here. Each word (or group of words) in the verbalizations matching up to a physical quantity is taken as an occurrence and each occurrence is characterized by its semiotic form. Tagging an occurrence with its semiotic form broadens the point of view about concepts: for instance we can take into account occurrences that cannot be considered as a physical quantity with certainty. Sometimes the semiotic form does not correspond to the standard scientific forms required for physical quantities, such as the physical quantities names, the usual symbols, the numerical values and units: the speaker may use a vague form or an inappropriate name: "it", "this", "electricity", "consumption", … In such cases it is not always possible to relate the occurrence to a well defined physical quantity and it can be categorized as "undefined".

A first set of questions is related to the occurrence of concepts: do students encounter and mobilize electricity concepts? Which concepts occur? We thus look for all occurrences of the electricity concepts. Figure 2 gives the list of the concepts encountered.

A second set of questions is devoted to the characterisation of the occurrences of concepts and of the working context. We characterise an occurrence of a concept by indicating who is the speaker, who introduces the occurrence (figure 1), what is the semiotic form of the occurrence (figure 3 gives a list of the semiotic forms used), if the occurrence participates to a relation between concepts, what is the grammatical mood of the occurrence, … For the working context, we take into account which tasks/activities are being performed, and with which persons, tools or resources do students interact?

The analysis of coded variables follows four directions. The first one is to look globally at each variable. At a second stage we look at the evolution of the way the students use the concepts. Another point of view is to cross the context variables with the occurrences of the concepts in order to determine a possible influence of the context. The analysis of the coded variables is also used to select records extracts for written transcription in order to perform a detailed analysis.

For example we look for the occurrences of the concept "electrical power". For one occurrence of this concept, the coding variables indicate that the "speaker" is "the students", that the one who introduces the occurrence is also "the students", that he refers to power using a unit (kilowatt) … About the context, we note that this occurrence occurs during data processing, using the data processing tool and that the teacher is not participating. This occurrence is one of the occurrences that we take into account when looking for the changes of semiotic form of electrical power during the students' work …

RESULTS

There were troubles with the school network and SCY-Lab, which provides the electronic environment of the mission to the students, was often not reachable. Therefore the students often had to use other tools and other resources than those designed for the mission. The students' environment was changed, providing unexpected and less controlled working conditions. The students used standard electronic tools, the scaffolding was mainly done by the teachers and the students turned to use internet their own way to seek for information instead of using the mission resources. As a consequence the teacher was very often in interaction with the students (30% of the whole sequence duration). This was not expected for this learning situation, but on the other hand we are able to compare the ways teachers and students use concepts.

Concepts mobilisation

The students mobilise the electricity concepts all along the working sessions. We observe periodic increases of occurrences of concepts at almost any stage of the students' work. However occurrences of concepts are numerous at all stages of the work except for the first 50 minutes when the students start with the problem and consider experiment design. The total number of the occurrences of electricity concepts is 680 over the 250 minutes of analysed records.

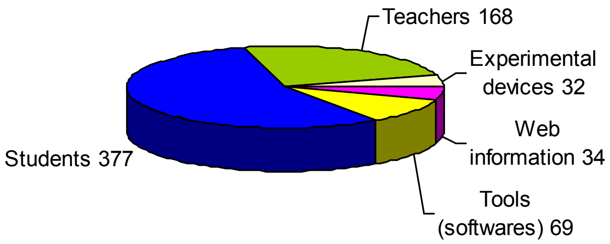

Fig 1: An occurrence of an electricity concept can be introduced by various participants. It can be introduced by a human participant such as students and teachers, as well as by a device or a document that the students use. For instance an occurrence of power is introduced by a document if a student reads and discovers it on the document, even if the true speaker is the

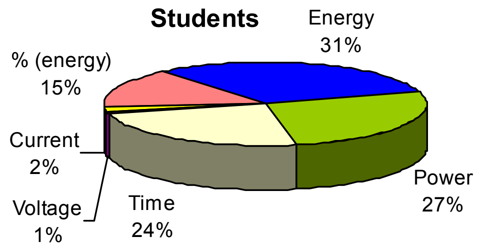
student. The number of occurrences is indicated for each participant.

Figure 1 shows that the number of occurrences due to the students (54%) is almost always more important than for any other source at any stage of the work. Occurrences are often brought by the teachers (25% of all occurrences) or by documents, tools and devices (20%). Lots of occurrences are probably due to the activities performed: measuring, seeking for information, making calculations … But this does not explain the abundance and regularity of the occurrences of concepts all along the work. In fact the students encounter strong and recurrent difficulties about concepts.

The students and the teachers use the same concepts. Furthermore they use a given concept in the same proportion compared to the occurrences of the other concepts: for instance the proportion of energy occurrences is about 30% of total concepts occurrences for both the students and the teachers.



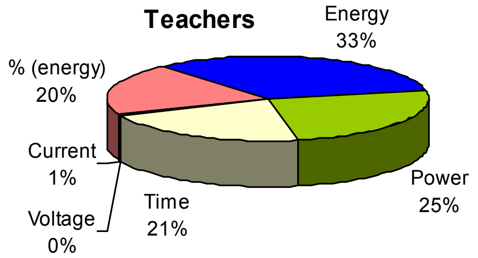


Fig 2: Comparison of electricity concepts mobilized by the students or by the teachers.

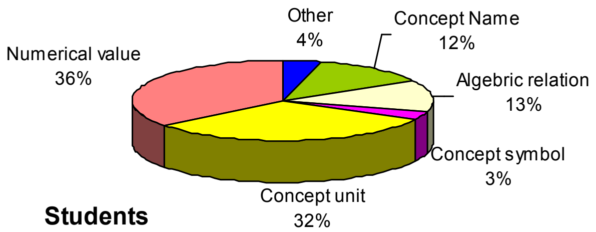
Semiotic form of concepts

On the other hand, the semiotic form of the occurrences of concepts is quite different for the teachers and the students (figure 3): the predominant form for the students is unit (32%) and numerical value (36%) since the scientific name of concepts is used only for 12%. For the teachers, the concepts name is 31%, unit 17% and numerical value 25%. A priori we may think that this can be due to the fact that the students and the teachers have different aims, since the teachers' main job is to guide the students while performing experiments, doing calculations … Despite this fact, the study of verbalisations shows that the students often use the unit name instead of the concept name. For instance one boy explained "there are several watts: there is the total watt, the sleep mode watt and the working mode watt", using the unit name watt instead of the concept name, power. In this example, the students discuss about power as if it was energy, suggesting that one can sum the power quantities in the same way than the energy quantities.



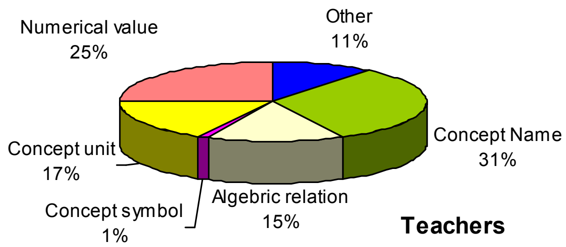


Fig 3: Comparison of the semiotic forms of concepts occurrences when concepts are used by the students or by the teachers.

The students' difficulties

In fact most difficulties encountered by the students concentrate around units. These difficulties have various origins, they occur at almost all stages of the students' work and they accumulate. This leads the students to debate and look for information. This explain (at least partly) the high level of the occurrences of the concepts all along their work.

The first main difficulty happens when the students interact with the measuring device during the experiment. It concerns the units and the meaning of these units, and therefore the meaning of the corresponding concepts and of the law linking the concepts. We count a very high value of concepts occurrences per minute for the interaction of students with the device: the students spend a short time using the device, but meanwhile concepts are particularly intensely used. One can think that this is because of measured values of physical quantities, but in fact the use of the device initiates a discussion about the physical quantities (the students use units names) to be measured. This leads the students to look for information on the web, and they encounter multiple difficulties in this activity.

The main difficulties are summarised below:

- The students have difficulties to adapt their strategy when then they are obliged to make some changes. For instance they plan to measure the energy consumed by the TV set when it is on and when it is off with sleep mode. Then it happens that the measuring device could not be used to measure energy the way they planned it. The students then turn to power measurements, but they deal with power the same way than initially planned with energy. It seems that they do not really figure out that power is not energy, and that time duration has a role to play. The relation between the two concepts is not mobilized. But probably the students do not really have a precise idea of the role played by time in their initial plan with energy.

- The students have to make links between the scientific world and the everyday life world. They have to use kW.h units and they have difficulties to understand that this is an energy unit. The energy unit they learn for the energy concept in physics is the joule. The unit kW.h is mostly used on electricity bills and electricity meters in everyday life, and probably 16 years old students are not familiar with this: the transcription reveals that they do not understand the raison d'être of such a unit. Furthermore they are mixed up between kW.h and kW/h: in everyday life French people usually pronounce "kilometer hour" for the km/h units instead of saying "kilometer per hour". Therefore kW.h sounds as kW/h at first for the students.

- The students have difficulties to interpret the meaning of the concept express from the unit: they really have to fight with the significance of kW.h and they discuss hard to understand what can be a kilowatt multiplied (or divided!) by time duration.

- The students do not mobilize their conceptual knowledge to solve a question. For instance in the discussion about kW.h, the students do not try to relate it to the $E = P * t$ relation, even if they know it (they refer to it in other circumstances). This may be due to the fact that they did not use this knowledge this way before and that they do not know much about the dimensional analysis practice.

- The students often use indifferently units names, units symbols and physical quantities symbols and sometimes numerical values. This leads them to confusion with laws in mathematical form. For instance they interpret w symbol (work) within an algebraic relation as the symbol for power unit (watt).

- Information collected freely on the web is difficult to interpret for the students. They find information but they often are not able to identify if this is the proper information or not. And they often cannot interpret the information they have selected. First the information is often abundant and varied, and thus this requires to perform a selection. Second it is most of the time not adapted to the students' conceptual knowledge level and skills: in the previous example the students encounter a concept related to energy that they do not know (work) and in this case they interpret it as power, because of the symbol confusion previously mentioned. In this case the information about work is available but they do not read it at first (they just pick an equation in a document including several pages), and when they do read the related explanation they could not understand it. This is also true when they do encounter the proper information they look for. A climax is reached when the students encounter erroneous information on the web (such as kW/h unit symbol).

In the given example, one can note that almost all the listed difficulties cumulate. This leads to a highly confusing situation, but this also leads the students to frequent discussions about the meaning of the physical quantity corresponding to kW.h and its link with power and time duration. These discussions engage them to experience spontaneously some kind of dimensional analysis. Apart from one boy, the students could not totally solve the point from these discussions, but they finally succeed when they really get engaged in the proper calculation and comparison of energy consumed by a TV set (for given durations when it is on or when it is off with sleep mode). The success in this case could not come from reflection (despite a great effort), but it comes through action.

At the end of the session, after several tries of data processing and with the teachers' guidance and assessment, the students reach the first correct result and it sounds as an answer to the problem they wanted to solve. From this point they are able to give sense to the appropriate strategy for data processing, and everything takes its place and goes the proper way as an evidence. At the end of the session, they go on totally by themselves, working for more detailed results after the end of the session, and dealing with concepts as experts could have done. Their final calculation sheet shows results with values, symbols and units organised in the most proper way.

CONCLUSIONS

Studying the way students use the concepts, it appears that the semiotic form of concepts occurrences may be interpreted as a marker of the students' conceptual mastery and of their understanding of the scientific task they perform. In this case study, the students start dealing with concepts through the experiment and this may explain the dominant and interesting role played by units names in the students' verbalizations.

The obstacles encountered by the students are multiple and difficult to predict. The free use of the web as a source of information appears to be highly problematic. The students often find information which is not adapted to their needs or which is erroneous. As novices, the students lack knowledge and skills that allow an expert to find his way even out of his domain of expertise (Schraagen, 1993). The students also need assessment to know if what they have done is pertinent, sufficient or correct. They often do not have enough ability to control and evaluate their activity and productions without help. We observe that they give up if they do not find any satisfying answer to their questions. Sometimes they go on with a task despite they know it is going a wrong way. Because the students could get enough help to pass the main obstacles, the difficulties encountered drive the group to share and question their conceptual knowledge, to argue and go deeper with the concepts, and to experience new scientific skills such as dimensional analysis. Therefore, on the point of view of the students' conceptual activity, this experience of an inquiry situation appears as rich and fruitful. This is due to a complex and fragile equilibrium between the students' motivation, their scientific skills level, the stimulation and hindrance of the encountered obstacles and the scaffolding they get from teachers. One can also guess that the fact that the students have (at the end) a clear feeling of the consistency and value of their work, has consequences.

A TYPOLOGY OF STUDENTS' KINETIC VIEWS OF CHEMICAL EQUILIBRIUM SYSTEMS

Ruth Wheeldon[1], Robert Atkinson[2], Alex Dawes[3] and Ralph Levinson[1]
[1]Institute of Education, London
[2]Highgate School, London
[3]JFS School, London

Abstract: Literature identifies the insufficiency of Le Châtelier's principle, and research describes a number of problems that students have in explaining and describing chemical equilibrium systems. In this study, questionnaires and interviews were used to consider the impact and extent of these issues for chemistry students in two schools. Thematic analysis through iterative coding of student responses resulted in the identification of 3 levels of explanation: A 'Holistic' level is when students describe how the behaviour of the microscopic and dynamic forward and reverse reactions affect each other resulting in system equilibrium properties; students explaining at the 'Mirrored reactions' level described the forward and reverse reactions behaviours as mirroring each other, but their combined system effect is not identified. For the remaining students, the forward and reverse reactions do not affect each other and are considered separately in explanations ('Reactions not connected' level). As many students do not offer 'Holistic' explanations, teaching strategies are suggested to enable students to develop such an understanding.

Keywords: equilibrium, particle theory, holistic thinking

BACKGROUND AND PURPOSE:

Teacher researchers identified extensive use of Le Châtelier's principle as an algorithmic device to solve problems related to chemical equilibrium processes. While Le Châtelier's principle has its uses in predicting macroscopic behaviour under certain conditions, its limitations are rarely acknowledged in schools. Solomonidou and Stavtidou (2001) identified applying Le Châtelier's principle to chemical systems before they reach equilibrium as such a limitation. The purpose of this research was to determine students' levels of understanding by probing their ability to explain such systems using particle interactions and dynamics.

As a proviso we recognise that chemists' explanations of equilibrium in chemical systems is more appropriately explained by changes in entropy but that at pre-university level the kinetic holistic understanding we have described will support such explanations when they are later introduced.

RATIONALE:

To identify strategies that can be used to enable students to explain the relationship between the microscopic and macroscopic behaviour in equilibrium system based on an iterative analysis of student explanations of such systems.

METHODS:

We designed a questionnaire in which students were asked to

a. Predict macroscopic effects in reversible chemical systems
b. Describe and explain the influence of rates of forward/reverse reactions on a system

c. Draw graphs to describe/predict the rates of forward and reverse reactions in the system.

101 students gave responses to one or more questionnaires in two different schools (A & B). To reduce bias in terms of the context of the chemical system, two papers containing exactly the same questions but referring to different contexts (see table 1) were given randomly to the students. The first questionnaires were given just after their first post-16 teaching of equilibrium which included reversible reaction systems and factors which affect equilibrium (June 2009). The second set of questionnaires was given after further teaching which considered chemical equilibrium systems in terms of K_p and K_c (November 2009) (Table 1).

Questionnaire	Chemical system(s) proving the context for the questions	Questionnaire timing (School A or B (numbers of pupils))		
		June 2009	Nov. 2009	May 2010
Q1	Ester – acid and alcohol system: $CH_3COOC_2H_{5(aq)} + H_2O_{(l)} \rightleftharpoons CH_3COOH_{(aq)} + C_2H_5OH_{(aq)}$	A (25) B (21)	A (11) B (19)	
Q2	Chromate - dichromate system: $2CrO_4^{2-}{}_{(aq)} + 2H^+{}_{(aq)} \rightleftharpoons Cr_2O_7^{2-}{}_{(aq)} + H_2O_{(l)}$	A (24) B (17)	A (19) B (18)	
Q3	For the same questions as Q1 & Q2 : Bismuth oxide chloride - bismuth trichloride system: $BiOCl_{(s)} + 2HCl_{(aq)} \rightleftharpoons BiCl_{3(aq)} + H_2O_{(l)}$ For additional questions: Nitrogen oxide – nitrogen oxide chloride system: $2NO_{(g)} + Cl_{2(g)} \rightleftharpoons 2NOCl_{(g)}$			A (28) B (32)

Table 1: Details of the questionnaire contexts chemical system contexts, administration timings and the numbers of pupils responding in each school

Approximately four months after the second questionnaire was administered, a sample of 13 students, were interviewed and were asked to:

a. Describe their general approach to answering chemical equilibrium problems
b. Describe the Haber process from a particle perspective
c. Account for their rates graphs drawn as responses in questionnaires 1 and 2.

All interviews were audio-recorded.

Later a third questionnaire was administered which covered the same questions as the first two using another context (see table 1) and a further two questions in a further context.

Through inductive analysis of questionnaire responses four researchers derived a coding system which was iteratively refined to identify three general levels of understanding of equilibrium systems. Interview responses were used to cross-check for consistency with responses from the questionnaires. We will use case studies to illustrate the nature of each of these types of understanding.

CASE STUDIES:

Holistic Understanding:

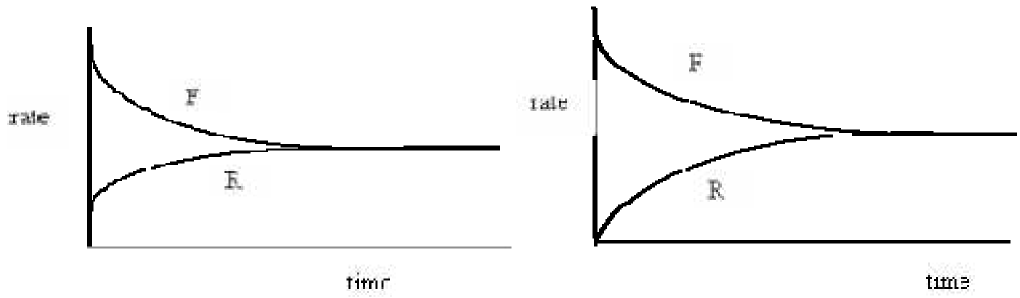
The forward and reverse reactions are described as affecting each other which results in the system equilibrium properties.

Ben (a pseudonym) is a high achieving student. He enjoys developing his thinking about the more challenging concepts.

His approach to equilibrium problems is to use mathematical relationships between the equilibrium constant and rate expressions. He describes his visualisation of a reversible chemical system in terms of colliding particles with the forward and reverse reaction occurring simultaneously. He uses Le Châtelier's principle alongside other approaches. He provided very detailed answers in all questionnaires and to interview questions. For example, Ben described the change in the rate of the forward reaction on the last questionnaire:

> *'As they react, their concentration will decrease due to dilution from the now formed products…the rate of reaction will decrease until dynamic equilibrium is reached…the rate of reaction will reach a constant value.'*

When asked to graphically represent changes in the rates of forward and reverse reaction he drew the graphs in Fig. 1 on his first two questionnaires (on the third questionnaire he drew one with the same key features as that for the second questionnaire).



Q1 Q2

Fig. 1: Ben's graphical responses in questionnaires Q1 and Q2 (F- forward reaction and R- reverse reaction lines).

Ben accounted for the difference between these two graphs in his interview by describing his first graph:

> *'To start with ….there is none of other one to react [product], so I should have really started that one [points to reverse reaction line] at zero then…..As they react the concentration of them [points to forward reaction line] goes down … and the concentration of them [points to reverse reaction line] goes up. So the rate of reaction, so less of it to collide … the rate of it [forward reaction] goes down and the rate of the other goes up for the same reason. After a while we reach equilibrium which means of course that the rates must be equal for each of them.'*

Mirrored reactions understanding:

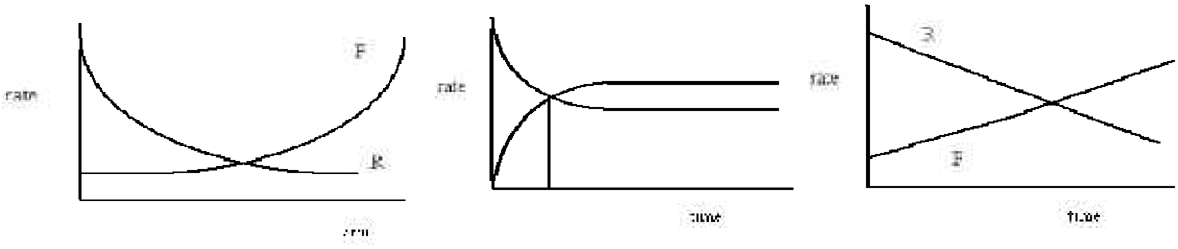
The forward and reverse reactions mirror each other, but their combined system effect is not identified.

Martin (also a pseudonym) attains middle grades in chemistry, which is the only science subject he took. He finds science subjects more challenging.

Martin’s approach to equilibrium problems is to use Le Châtelier’s principle. He describes his visualisation of a reversible chemical system in terms of colliding particles focusing on the forward reaction. For example, Martin described the change in the rate of the forward reaction on the second questionnaire:

> *‘The rate of these will decrease and increase until the rate of the forward reaction and the rate of reverse will be equal and then the equilibrium has reached a dynamic equilibrium.’*

When asked to graphically represent changes in the rates of forward and reverse reaction he drew the graphs on his questionnaires (Fig. 2):



Q1 Q2 Q3

Fig. 2: Martin’s graphical responses in questionnaires Q1, Q2 and Q3 (F- forward reaction and R- reverse reaction lines where indicated).

Martin accounted for the shape of his first two graphs in his interview:

> *‘As water is added you get more and more of the product… You finally reach a point of a dynamic equilibrium, where the rate of forward reaction and rate of reverse reaction are completely equal. …… reactants are reacting considerably more because the rate of the forward reaction is much greater…… When lines hit on this one [graph Q2] is point of dynamic equilibrium…’*

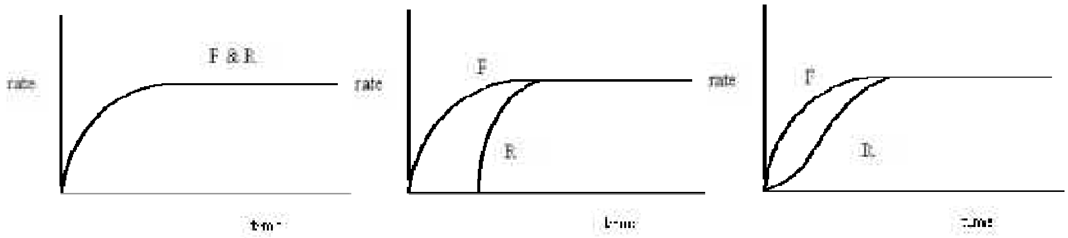
Reactions not connected understanding:

The forward and reverse reactions do not affect each other and are considered separately.

Here we consider Anna’s (pseudonym) responses to describe the features of this sort of understanding. Anna achieves A and B grades and likes chemistry, which she needs to study as a prerequisite to study Medicine. Her approach to equilibrium problems is to apply Le Châtelier’s principle. She identifies key knowledge and draws on algorithms. When visualising a reversible chemical system she notes the bonds that are broken or made in the forward reaction before considering those in the reverse reaction in a stepwise fashion. Her use of key knowledge is illustrated in her response when asked to describe the change in the rate of the forward reaction on the second questionnaire:

> *‘At equilibrium the rate of reaction is constant.’*

When asked to graphically represent changes in the rates of forward and reverse reaction Anna drew the graphs shown in Figure 3 on her questionnaires:



Q1 Q2 Q3

Fig. 3: Anna's graphical responses in questionnaires Q, Q2 and Q3 (F- forward reaction and R- reverse reaction lines).

Anna accounted for the shape of her first two graphs in her interview:

> *'I knew [forward reaction]….. the concentration would decrease and then level out. So the rate of reaction would increase and level out... It obviously has to start at zero because nothing is happening then it's got to increase to the point it would be at dynamic equilibrium…..[reverse reaction] has to start at zero as well and it also has to level out because when it is in dynamic equilibrium, the rate of reaction is constant. And the whole point of dynamic equilibrium is the rates of reaction are the same…… They have to be on the same line, because they have to be the same value.*

When asked about the difference between Q1 and Q2 graph Anna responded:

> *'The first reaction is happening… It's not quite produced enough of the product, so you have to wait a bit of time for the [reverse] reaction to start happening...'*

FINDINGS:

Twenty-three of all students (57) completing the final questionnaire (Q3) responded in a manner consistent with 'Holistic' thinking. Twenty-one of these 57 students provided explanations that indicated thinking about the forward and reverse reactions as 'Mirrored reactions' and the remaining students (13) did not show that they were connecting forward and reverse reactions in their responses (Fig. 4).

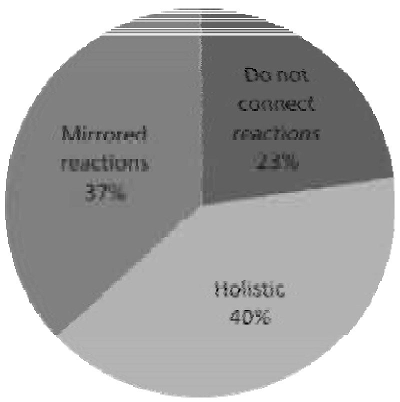


Fig. 4: The distribution of types of understanding of reversible chemical systems identified from the final questionnaire responses.

CONCLUSIONS AND IMPLICATIONS:

There was evidence that at the end of their equilibrium course 40% of students were able to view the chemical system holistically, when they can account for variations in rates of reaction using either/or mathematical relationships or particle interactions . These students will be able to explain equilibrium phenomena beyond the limitations associated with a reliance on Le Châtelier's principle. The other 60% of students, however, will experience difficulties in doing so.

Given that 22% of students demonstrated holistic understanding after initial teaching and that then only a further 19% of students were able to develop this understanding with further teaching, which is modelling chemical equilibrium systems via mathematical means, suggests that they do not have sufficient representational resources to flexibly manipulate aspects of the chemical equilibrium system (Raviolo and Garritz, 2009). It is clear that students need further support in modelling chemical systems which explicitly interconnect the macroscopic with the microscopic or particle interactions (Maia and Justi, 2009). Such an approach would include these stages:

a. The fundamental view of particle theory that the macroscopic behaviour of systems can be accounted for by particle behaviours;
b. Dynamic particle models, for example, role play or computer simulations (for example, PhET Interactive Simulations (2010)), where students note the changes in the rates of the forward and reverse reactions alongside the macroscopic effects.
c. Encouraging students to explain changes in chemical systems in terms of dynamic particle interactions.

STUDENTS' SENSE-MAKING OF ELECTROMAGNETIC INDUCTION: A SEMIOTIC ANALYSIS

Jennifer Yeo[1]
[1]Nanyang Technological University, Singapore

Abstract: Visualization plays an important role in the conceptualization of electromagnetic induction. The ability to visualize what goes on in an electromagnetic induction phenomenon using culturally consistent semiotic resources is a crucial determinant to successful problem solving. Understanding how students make sense of electromagnetic induction phenomenon with semiotic resources should thus be an important aspect in studies of students' conception of electromagnetic induction. In this paper, I propose the use of social semiotics as a lens to understanding students' conception of electromagnetic induction. In particular, the framework of systemic functional linguistics is applied to multimodal texts to study two students' meaning-making of a problem on electromagnetic induction and hence their conception of electromagnetic induction. It was found that while the two students solved the problem successfully, their sense-making of the phenomenon with semiotic resources was different. The choice and use of semiotic resources was indicative of how they conceived the idea of electromagnetic induction. It is thus concluded that a semiotic analysis framework is useful to understand students' conception of EMI.

Keywords: scientific visualization, electromagnetic induction, social semiotics

INTRODUCTION

Electromagnetic induction (EMI) makes extensive use of visual imagery to theorize the production of current when a conductor experiences a change in magnetic field (Rieber, 1995). In a similar vein, students need to appropriate these visual tools in thinking and exploring the phenomenon of EMI. Students' ability to use these culturally-consistent tools in making sense of EMI should thus be one key factor when considering students' conceptualization of the topic.

While there have been extensive studies done on students' conceptions of EMI (e.g., Maloney, O'Kuma, Hieggelke, and Heuvelen (2001), Saglam and Millar (2006)) which have produced a comprehensive list of content-specific difficulties that students have with EMI, it may not inform any specific competencies in the use of representations that students need in making sense of EMI phenomenon. Yet, visualization studies in science education mostly focus on measuring students' visual-spatial capability using instruments adapted from educational psychology (e.g., Purdue visualization and rotation test (Bodner & Guay, 1997)). These tools, based on cognitive theory, may not provide much useful information about students' ability to recognize cultural-specific visual tools, use them to communicate information or apply them to solve problems. An alternative perspective based on social semiotics theories may provide illuminating insights instead. However, such studies on scientific visualization are few. The goal of this paper is thus to propose an analysis framework based on social semiotics to study students' visualization of EMI and to use it to understand students' conception of EMI. The research question that I ask is "what meanings of EMI were made by students using semiotic tools?"

THEORETICAL FRAMEWORK

Social semiotics is a branch of study that perceives signs and symbols to be imbued with a meaning by community/context which in turn shapes the context in which these representations are used (Halliday & Hasan, 1985). Scientific visualization can thus be conceived as symbols or signs constructed or transformed and used by scientists as material and social tools in understanding and developing the scientific field. For example, lines of force, drawn to represent intensity and strength of a magnetic field, have been used as materials tools for scientists to think about its interaction with electrons and served as communication tools to support social discourse among scientists about EMI. These signs and symbols made up of language, gestures, iconic figures could express different levels of representations: macro (physical objects), micro (inferred "objects") or symbolic (symbols and equations) (Gilbert, 2007). They form a cultural-specific semiotic system that characterizes the scientific community through which scientific meanings are construed.

Based on the framework of systemic functional linguistics (Halliday & Hasan, 1985), different forms of meaning can be construed with semiotic resources (Lemke, 1998). The selection, usage and combination of these resources can provide information about the events and relations one makes (*presentational* meaning), the attitude one has towards the content and others (orientational meaning) and the degree of coherence of the text (*organizational* meaning). Table 1 summarizes how the three metafunctions of semiotic resources can guide the analysis of students' meaning-making of scientific phenomenon with semiotic tools.

Table 1: Description of three metafunctions of semiotic resources

Presentational	*Orientational*	*Organizational*
Identifies kinds of relations construed among semiotic resources in terms of events and relationships (e.g., Φ = BA indicates identifying relations)	Identifies the kinds of semiotic resources used in meaning-making (e.g., symbols and graphics) and level of representation	Identifies how semiotic resources are organized (e.g, figure of a coil and pictorial lines of force show the spatial arrangement of Φ, B and A

METHOD

This section reports the sense-making of EMI by two Grade 12 students, Peter and Nancy, chosen at random, during a think-aloud protocol interview. This interview was conducted after lectures on EMI were completed. Instruction on EMI includes demonstration of EMI experiments and visual-rich graphics to explain the concept of EMI at the macro (physical objects), micro (effects on electrons) and symbolic (formulas) levels of representation. During the interview, the students were encouraged to draw, write, say or use objects as representations to explain their solution. The interview was video-recorded to capture the use of semiotics during problem-solving, transcribed and analyzed according to the framework shown in Table 1. The problem given is shown in Figure 1.

Problem:

A copper disc spins freely between the poles of an unconnected electromagnet as shown in the figure on the right.

Describe and explain what will happen to the speed of the rotation of the disc when a direct current is switched on in the electromagnet.

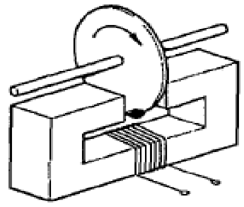

Figure 1. Problem of an EMI phenomenon

STUDENTS' MEANING-MAKING OF ELECTROMAGNETIC INDUCTION PHENOMENON

The two students predicted correctly that the copper disc would slow down when a current flowed in the solenoid. However, they made sense of the phenomenon differently. Figures 2 and 3 show excerpts of their explanations given by the two students, Peter and Nancy.

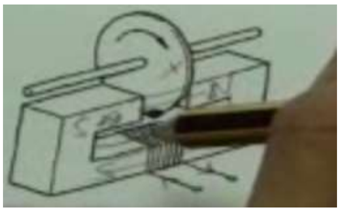
(i)

… this is a particular *point* before it was subjected to this magnetic field lines …

(ii)

Same situation when the magnet is try to enter a coil … Before you try to enter … this *copper disc* … will try to oppose the change …

(iii)



… it's the same as the pulling the magnet out of the coil … will like induce another e.m.f. … attract *this point* back to the magnetic field.

Figure 2. Peter's meaning-making of EMI phenomenon

Using drawings and gestures as representations of specific and observable objects and processes of the phenomenon (refer to Figure 2), Peter identified "a particular point" on the disc (by pointing out a specific physical point on copper disc as in (i)) to be in the "same situation when the magnet is try to enter a coil" (as he used his fingers to curl like a coil of wires in (ii)). Drawing parallel to a magnet pulling out of a coil, he concluded that the copper disc "will … induce another e.m.f". Although Peter was able to predict correctly the effect on copper disc, he was merely drawing associative relations to an event he had encountered, drawing upon concrete objects and processes in his sense-making of the phenomenon rather than culturally-specific representations.

(i)		I think about the *particle* inside this rotating disc … the *electrons* … into the page …
(ii)		so there is a *current* is going out of the page… so there will be *force going downwards*.
(iii)		Current is induced by the *movement of electrons*. … it's (disc) slow down … because of *current flowing upwards* …
(iv)		then there will be *force going out of the page* … so it will be slowing down.

Figure 3. Nancy's meaning-making of EMI phenomenon

Nancy, on the other hand, made different types of meaning of the phenomenon and at different levels of representation (refer to Figure 3) compared to Peter. Although the modes of representations (i.e., graphics and gestures) were similar, Peter's diagrams and gestures were representatives of physical objects/parts in the experimental set-up in the problem (macro level) while Nancy used pictorial representation of an electron (refer to enlarged dot in (i)) and gesture (Fleming's left hand rule) to indicate relationship between direction of forces, current and magnetic field in Figures 3(ii) and (iii)). With these semiotic resources, Nancy drew consequential relations about the direction of current flow as she considered the motion of the enlarged dot drawn, and causal relations as she deduced the subsequent motion of the electron resulting from its motion in a magnetic field using Fleming's left hand rule. Here, drawings, hand gestures and language have mediated Nancy's construction of the invisible events happening to equally microscopic objects. Unlike Peter's meaning-making of the phenomenon, Nancy's involved imageries consistent to those of EMI.

DISCUSSION AND CONCLUSION

Science is not constructed on verbal language alone (Lemke, 1998). The ability to visualize what goes on in an EMI phenomenon with culturally consistent multi-modal resources is an important determinant to successful problem-solving. The analysis framework proposed in this paper helps to illuminate the differences in meaning-making between two students, albeit predicting the outcome of the phenomenon correctly. The study on the kinds of semiotic resources used by the students by drawing inferences to the kinds of meaning made, the levels of representations and coherence of their sense-making was able to provide evidence about students' conceptual understanding of the EMI. It is obvious that Nancy's fluency in transiting between macro and micro levels of representations using different kinds of semiotic resources as she considered the effect on a moving electron in a copper disc (micro) as the copper disc rotated (macro) was more consistent with the kinds of cultural-specific tools used to think about EMI phenomena. Gilbert (2007) describes this fluency in visualization involving the ability to acquire, monitor, integrate and extend learning from representations as metavisualization. Peter's visualization, on the other hand, was mainly that of associative relations as he focused on macro representations (a point on copper disc indicated by pictoral symbols) in his visualization and making association with equally concrete experiences he had come across. Such meaning-making pattern tends to be less generalizable to other situations and may be an indication of possible difficulties with the use of representations consistent with the field of study. The difference in the levels and types of representations used by the two students – Nancy shifting between macro and micro levels using cultural-specific representations while Peter relying mainly on macro objects and events – during problem solving could perhaps point to another source of difficulty students might have with EMI, thus extending the comprehensive list of conceptual difficulties students have with content-specific concepts already established. Thus, a social semiotic analysis could thus be useful in identifying a student's competency in using the appropriate levels of representation in his/her sense-making of an EMI phenomenon.

Abstract: The aim of the present study was to investigate if students use causal relational reasoning using density in explaining floating/sinking (F/S) phenomena before, during and after the implementation of a Teaching/Learning Sequence (TLS). The study is part of a cross-national research-based curriculum project on Materials Science. One of the theoretical bases for the design of the TLS was focused on a model-based learning approach. The TLS was designed and developed by researchers working in close collaboration with school teachers comprising a University – School partnership. Its implementation took place in two science classrooms of forty-one 5th graders (mean age 10.9; *SD* =.376) in total. Participants answered 5 tasks (pre, during, just after and seven months after the implementation) on explaining F/S phenomena using the concept of density. A significant shift on participants' conceptual understanding was evident; participants grasped the scientific concept of density after the intervention. In addition, it seems that a significant number of participants could successfully explain F/S, using causal relational reasoning. Finally, participants who managed to use density in a causal relational reasoning had a significantly better understanding of density as a property of materials than those who used density in a causal linear reasoning.

Keywords: Model-based learning, Causal relational reasoning, Concept acquisition, Density, Floating/Sinking phenomena

BACKGROUND, FRAMEWORK, AND PURPOSE

Model-based reasoning can be thought of as a continuum in which teachers begin with students' basic representational capacities and try to end up near the practices of scientists (Nersessian, 2008). An important constrain in this transition is the narrow range of students' causal models. Most of them tend towards simple causal models in explaining phenomena. For instance, when they try to explain F/S of an object, they focus only on the object, giving answers such as "it sinks because it is heavy" (Kohn, 1993). However, many concepts and theories in science depend on substantially more complex causal models (Perkins & Grotzer, 2005). Causal relational reasoning, being such a complex model, in the case of F/S provides interpretations such as "if an object has bigger density than a liquid then it sinks". Perkins & Grotzer (2005) argued that cultivating greater complexity in students' causal models leads to better understanding of phenomena and relevant concepts that are used to interpret them.

Moreover, there is a considerable agreement that density is an abstruse notion for students. Students, before being exposed to the systematic teaching at schools, have already developed a conceptual framework about matter and material kind, which differs from the scientific one (Smith, Snir & Grosslight 1992; Hardy et al. 2006; Wiser & Smith 2008). Within students' conceptual framework, the concepts of weight and density are undistinguished

(Fassoulopoulos, Kariotoglou & Koumaras, 2003). Moreover, students by referring to the density of an object, they focus on only one feature of the object, either on the weight, the size or the shape, (Smith, Snir & Grosslight, 1992). Smith et al. (1992) also argued that the necessary condition to conclude that students have grasped the concept of density, in an elementary level, is to realize that the heaviness of the kind of material is a property of that material. In addition, they claim that this is a prerequisite in order to argue that students can distinguish the concepts of weight and density.

RATIONALE

Although the concept of density is considered among the most difficult concepts for primary school students, there is little empirical evidence of (TLSs) (Méheut & Psillos 2004), that use the model-based reasoning to help students to abandon the constraints of the linear causal reasoning (Perkins & Grotzer, 2005). In this study, we were keen to answer the following research questions: (a) In what extent do students acquire density as a property of materials? (b) Do students use causal relational reasoning in explaining F/S? (c) Does the use of complex causal reasoning help students to understand the concept of density? For this purpose a five unit TLS on density as a materials property (Spyrtou, Zoupidis & Kariotoglou, 2008) has been developed.

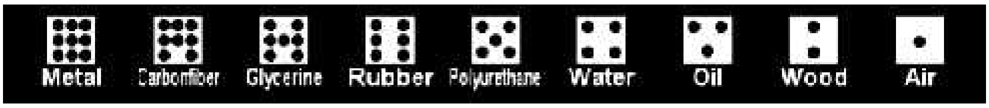

Fig. 1: The visual "*dots-in-a-box"* model of several materials

More specifically, in the 1st unit of the TLS, participants were introduced to the technological problem of the salvage of the *Sea Diamond*'s shipwreck through a video which included a description of the accident and a discussion about its environmental consequences. Furthermore, the participants were familiarized with F/S phenomena and the relevant concepts through several activities, such as real experiments, working in a Predict-Observe-Explore (POE) approach. In the 2nd unit, the participants working in groups, followed the POE approach in real and simulated experiments in order to identify and test possible variables that affect F/S, for instance, the weight of an object and the kind of the liquid's or the object's material. In the 3rd unit the participants were introduced to a visual model of density as a property of material, the "dots-in-a-box" model (Smith, et al., 1992, Figure 1). Using this representation in relevant simulated experiments we expected that the participants would acquire a causal relational reasoning (Perkins & Grotzer, 2005) in order to explain and predict F/S phenomena for homogenous objects. In the 4th unit, participants used the visual model to come to a conclusion about the F/S of two-materials composite objects, for instance a bottle filled with air or a bottle filled with water. By doing this, we aimed to help participants to understand that the density of a composite object, which consists of two materials, lies between the densities of the two materials. Finally, in the 5th unit, participants had the opportunity to work in groups in a simulated environment and to investigate the F/S of the *Sea Diamond* cruise ship, in order to argue about its salvage.

METHOD

This study was conducted in two 5th grade science classrooms. Forty one 5th graders (mean age 10.9, *SD* =.38) participated in the study. Each of the five units of the TLS lasted for 2 teaching periods of approximately 80 min in total. The implementation took place during normal daily courses and the female class teacher had great experience in teaching science.

Data Collection: Data were collected from multiple sources. For the sake of conciseness, in this paper we will be limited in presenting the results only of the analysis of the learning of density as a property of materials (Tasks 1, 2 and 3), as well as the use of causal relational reasoning in explaining F/S (Tasks 4 and 5) of the pre (just before implementation), interim (between 4th and 5th unit), post (just after implementation) and post-post (seven months after implementation) phases of evaluation. More specifically, task 1 asked participants to write a sentence including the words density and material. Task 2 asked participants to choose and explain their choice, on which of two objects of the same amount and material, but of different shape has bigger density, or if they have the same density. Task 3 asked participants to choose and explain their choice, on which of two objects of the same material, but of different size has bigger density, or if they have the same density. In task 4 participants were asked to draw a big sphere and a small triangle in their final position in a liquid, taking into account the densities that are given in “dots-in-a-box” representation (sphere’s material: two dots, triangle’s material: six dots and liquid’s material: four dots). They were also asked to explain their drawings. Finally, in task 5, participants were asked to choose and explain their choice, about the final position of two identical spheres in a liquid, taking into account the densities that are given in “dots-in-a-box” representation (object’s A material: two dots, object’s B material: three dots and liquid’s material: four dots). The first choice was that the two objects are floating at the same level, the second that object B floats in a higher level than object A and the third choice is that object A floats in a higher level than object B. Tasks 1, 2 and 3 were addressed to participants in each of the four phases (pre, interim, post and post-post) of the TLS, while tasks 4 and 5, only in the last three phases.

Coding: Answers in tasks 1, 2 and 3 were classified in four categories, and in tasks 4 and 5 in two categories, by two independent judges, with 85% agreement which after a discussion was increased to 100%. The same categories were used in the tasks 1, 2, and 3. Phenomenological, incomplete or no answers were classified in the “no answer” category (0). Answers that accepted density as dependent on the object’s size, (e.g. “the big object has bigger density”), were classified in the category “extensive idea” and they were credited with one (1). Answers that accepted density as a property of materials and dependent on the object’s size, (e.g. “the objects have the same density because they are made from the same material and the same quantity”), were classified in the category “transitional idea” and they were credited with two (2). Finally, answers that considered density as a property of materials, (e.g. “both objects have the same density because they are from the same material”), were classified in the category “intensive idea” and they were credited with three (3). The means of the classification in these three tasks were calculated and rounded for each student.

Answers that were based on causal relational reasoning to explain F/S, (e.g. “object A floats because its density is smaller than the liquid’s and object B sinks because its density is higher than the liquid’s”), in task 4, were classified as “causal relational” and credited with one (1). Additionally, answers that used causal linear reasoning, “(e.g. object A will float because it is light and object B will sink because it is heavy”), were classified as “causal linear” and were credited with zero (0). Answers that used causal linear reasoning in task 5, (e.g. “they both float because they are light”), were classified as “causal linear” and were credited with zero (0). Additionally, answers that used causal relational reasoning to explain F/S, (e.g. “I choose the third picture because both objects have smaller density than the liquid and object B has bigger density than object A”), in task 5, were classified as “causal relational” and were credited with one (1). The means of the categorization in the last two tasks were also calculated and rounded for each student.

RESULTS

Table 1 presents the participants' progress in understanding the concept of density as a property of materials. As it was expected, the number of participants that considered density as a property of materials increased significantly after the first and second part of our implementation (interim and post measure), while the number of participants answering irrelevant, phenomenological or incomplete answers decreased significantly from the pre to the post phase of evaluation (Wilcoxon Signed-Rank Test, z=4.8, p <.001). Furthermore, the pattern of answers remained unchanged from post to post-post evaluation (Wilcoxon Signed-Rank Test, z=.29, p =.770). Nevertheless, a small though considerable number of participants were still assuming that density is an extensive quantity (category 1).

Table1. Frequencies of participants found in each category in each time-point concerning learning of density as a property of materials

Tasks 1, 2 and 3	**Time-points**			
Categories	**pre**	**interim**	**post**	**post-post**
3: Density as a property of materials (intensive idea)	0	10	13	11
2: Density as a property of materials and dependent on the shape, weight or size of the object (transitional idea)	1	7	4	7
1: Density dependent on the shape, weight or size of the object (extensive idea)	8	13	17	15
0: Phenomenological, incomplete or no answers	32	11	7	8
Total answers	41	41	41	41

The results concerning participants' explanations of F/S phenomena are shown in table 2. These results are based on participants' answers in Task 4 and 5, which were conducted only in interim, post and post-post phase of evaluation.

Table2. Frequencies of participants found in each category in each time-point concerning participants explanations of F/S phenomena

Tasks 4 and 5	**Time-points**		
Categories	**interim**	**post**	**post-post**
1: Use of density in a "causal relational" reasoning	17	22	15
0: Use of density in a "causal linear" reasoning	24	19	26
Total	41	41	41

A considerable number of participants (seventeen out of forty-one) were able to use density in a causal relational reasoning after the first phase of our implementation in the intermediate phase of evaluation (see Table 2). This number was significantly increased in the end of the TLS where almost one out of two participants used density in a causal relational reasoning (Wilcoxon Signed-Rank Test, $z=2.7, p <.05$). However, this improvement lost at the post-post time point, seven months later, and participants started using density in a linear reasoning again (Wilcoxon Signed-Rank Test, $z=2.4, p <.05$).

Mann-Whitney non-parametric analysis was used in order to test our hypothesis that cultivating causal relational reasoning in explaining F/S phenomena could lead to better understanding of density as a property of materials. More specifically, we divided our participants in two groups; those who in each time-point understood and used causal relational reasoning and those that used causal linear reasoning in explaining F/S. For each group of participants we calculated the means corresponding to their conceptual understanding of density as a property of materials. As we expected, significantly more participants who used causal relational reasoning, understood density as a property of materials, than participants who used causal linear reasoning in interim ($p =.040$), post ($p =.007$), and post-post ($p =.001$) phase of testing.

CONCLUSIONS

The results showed statistically significant increase of the participants who understood density as a property of materials, which remained stable seven months later (Table 1). Furthermore, there were a considerable number of participants who used density in a causal relational reasoning to explain F/S phenomena (Table 2). In parallel, the number of participants who used causal relational explanations in the post phase of evaluation significantly increased, in comparison with the interim one. One possible explanation for this improvement could be the use of the *Sea Diamond's* cruise ship simulation, in the 5^{th} unit. In this unit participants used the *Sea Diamond* cruise ship simulation in order to investigate the conditions under which a ship sinks and floats, in the frame of the technological problem solving of the salvage of the sunken ship. Nevertheless, this improvement did not remain seven months later. An explanation of that could be the short period given to such activities, that is, only a part of the last unit of the TLS. Last but not least, we noticed that participants who managed to use density in a causal relational reasoning had a better understanding of density as a property of materials, in a statistically significant degree, than those who used density in a causal linear reasoning. We consider that this result is in favor of Perkins & Grotzer (2005) claim, that cultivating complex causal reasoning can enhance participants' concepts' understanding.

ACKNOWLEDGMENT

Work presented in this paper has been supported by the EU through the ECRDG in the project *Materials Science* –University-school partnerships for the design and implementation of research-based ICT-enhanced modules on Material Properties, Science and Society Programme, FP6, SAS6-CT -2006-042942.

SCIENCE TEACHER TRAINING THROUGH AN IBL EXPERIENCE

Ariza, M.R.[1], Quesada, A., Abril, A.M., García, F.J.

[1]Department of Didactic of Sciences. University of Jaén

Abstract: Educational research has revealed that inquiry-based learning (IBL) methodologies facilitate science understanding and the development of scientific competences, offering strategies to overcome academic failure and to ensure students' scientific literacy. A review of the Spanish projects with a focus on science education carried out in the last twenty years, shows very few initiatives explicitly based on the application of IBL approaches, pointing out a potential way to improve science learning. In the present paper, we describe a work aimed at promoting IBL methodologies among teachers. The main purpose is to make prospective teachers aware of the benefits associated with this kind of pedagogies, through offering them the opportunity to live an IBL experience and to reflect from practice.

Keywords: Science education, science learning, scientific process skills, IBL, teacher training.

INTRODUCTION: BACKGROUND, RATIONALE AND PURPOSE

The implementation of the "Lisbon Strategy" and the subsequent "Education and Training 2010 work program" are causing many changes in most of the European educational systems. The report "Educational system and human capital" published by the Spanish Economic and Social Council (1) in 2009, claims that "the high percentage of students' failure is connected with internal factors like the use of teaching methodologies with few practical applications of knowledge and the limited pedagogical training of teachers...". As a consequence, experts have suggested that a reflection about current pedagogical models, which are mainly based on lecturing and involve very little knowledge transfer, should be made, prompting the evolution towards new teaching methods.

IBL in Science Education

The current educational research along with the publication of several national reports, reveal the necessity to look for new approaches to science and mathematical education. There is a great deal of evidence showing not only a lack of students' motivation towards science and mathematics (Rocard, 2007), but also that science learning often becomes a "transitory experience with little application to future thought and action" in students' lives (National Research Council, 2000: 121).

With respect to the learning of mathematical and scientific knowledge, it is usually obstructed by inadequate students' preconceptions about natural phenomena, by the lack of significant instructional contexts to promote situated and transferable learning and by the abstract nature of many scientific theories and models (Ariza and Quesada, 2010). As a consequence of this disparity between students' prior ideas and theories, research has repeatedly shown that students learn normative knowledge in a superficial way, just to face or deal with school activities and exams. However, they are unable to apply scientific theories to explain real world phenomena, and their preconceptions persist after years of instruction (Franco and Taber, 2008; Taber, 2002).

Meaningful acquisition of scientific theories is promoted through active, collaborative, and inquiry-based learning (IBL), in authentic contexts. According to the National Research Council (2000), inquiry-based teaching may be understood as the experiences that help students acquire concepts of science, skills and abilities of scientific inquiry, and understanding about scientific inquiry. The American National Science Education Standards describe inquiry in education as “a multifaceted activity that involves making observations; posing questions; examining books and other sources of information to see what is already known; planning investigations; reviewing what is already known in the light of experimental evidence; using tools to gather, analyze, and interpret data; proposing answers, explanations and predictions; and communicating results. Inquiry requires identification of assumptions, use of critical and logical thinking, and consideration of alternative explanations”. (p. 23)

IBL in the Spanish context

In Spain, there is great deal of didactic projects to improve mathematics and science learning. An analysis of the theoretical backgrounds underlying these projects shows a predominance of constructivist claims. Nevertheless, though not explicitly embraced, the IBL paradigm is somehow present in some of the pedagogical features guiding these approaches. One of the very few initiatives explicitly mentioning the use of Problem Based Learning (PBL) and IBL, is that carried out by Bárcena and Ibáñez (2) (1991-2001) or by Sierra in 2004 (3). However, it must be said that although these projects led to interesting learning experiences or resulted in valuable pedagogical materials, they might be considered as isolated initiatives carried out in a limited time spam, with no continuity, or with none or very little impact on the national context.

IBL for teacher education

Research on effective learning and learning environments has proved that IBL methodological approaches foster inquiring minds and scientific attitudes in students. However, although inquiry promotes deeper science and mathematics understanding teachers may find obstacles planning and applying this methodology successfully (Olson and Loucks-Horsley, 2000). Furthermore, in Spain, there is a lack of explicit training on IBL methodologies in teacher initial education, both for primary and secondary schools. Thus, for in service teachers the implementation of inquiry learning in classrooms entails a number of significant challenges. Teacher education institutions are expected to provide opportunities for teachers to develop not only knowledge and skills as future educators, but also a good and a deep understanding of learning processes and approaches to create better learning environments for their students.

In this paper, we describe a work on science teacher training carried out using an IBL experience, designed and developed under the PRIMAS (4) framework.

Purpose

Taking into consideration the aforementioned, the objectives underlying our pedagogical approach are:

- Promoting positive attitudes towards science and mathematics learning.
- Developing inquiry skills in students, making them lifelong learners and inquirers.
- Increasing students’ engagement in their own learning process, (active and more autonomous learning).
- Making sense of scientific ideas and mathematical tools and showing their value to understand and explain the world.

- Helping prospective teachers to recognize the pedagogical value of IBL approaches, experiencing them as students and reflecting from practice.

Therefore, the purpose of our pedagogical approach is twofold: on one hand, to offer a challenging problem or situation which students (undergraduate primary school teachers) have to tackle and solve. In order to do so, they will have to develop and apply inquiry skills and make sense of science and mathematics concepts. On the other hand, since the intervention is implemented in initial teacher training, we intend to make prospective teachers aware of the pedagogical value of IBL activities, while experiencing them as students.

METHODOLOGY

The pedagogical approach being described has been implemented for four academic years (2007-2011) in an undergraduate science education course for prospective primary school teachers (teacher initial education).

Over 600 hundred undergraduates (20-22 years old) have gone through this instructional intervention, making it possible to refine it after any implementation cycle. The work has been developed within a FP7 European project aimed at promoting IBL in Mathematics and Science Education across Europe and the full activity may be downloaded from the project website (5).

The classroom activity involves three sessions (2 hours each), although the timing may vary slightly from one group to other.

Session 1

The first session involves three main objectives:

- Introduce the activity to students in a motivating and engaging way
- Encourage students to work in teams, discuss, design and plan their group work
- Supervise the experimental design made by each group of students, and offer some feedback or guidance about it.

The main purpose of the experiments proposed by students is to gather evidence and to provide foundation for their decision-making when dealing with the initial problem. Thus, an appropriate experimental design should offer answers to key guiding questions and takes into account the control of variables, making it possible to draw interesting conclusions afterwards.

At the end of the first session, teachers supervise the experimental design made by each group. Teachers should use challenging and guiding questions as a valuable instrument to promote students reflection on the appropriateness of their experiment. The main idea is to offer the minimum help to allow autonomy and self-regulation but at the same time, to avoid frustration or the promotion of non profitable ways of working.

Session 2

In the second session, students will carry out the experiments they have previously designed to test their initial hypothesis. In order to do so they will have to:

- Establish experimental conditions and differentiate between dependent and independent variables
- Make measures and acquire data
- Handle lab tools and equipments and get familiar with their appropriate use
- Decide upon the best way to organise and represent data.
- Analyze results
- Draw conclusions based on the available evidence

Session 3

The third session involves three objectives:

- Making students familiar with the production of a scientific report
- Promoting communication skills through the performance of oral presentations
- Encouraging discussion and debate on experimental results

Students must make a report including all the relevant information associated with their investigation and present their report to the rest of the class. The scientific report should include the following sessions: title, authors, abstract, keywords, introduction, methodology, results, conclusions and references.

Students may use specific software to assist them in the presentation and discussion of their work. After any of the presentations, teachers must encourage students to criticize and discuss their mates' work in a constructive way.

RESULTS

The implementation of the instructional intervention has promoted a high level of students' participation and engagement. Although it has always been offered as optional, over 80% of students took part in it, offering positive feedback about the experience.

The IBL activity offers an appropriate context to develop inquiry skills associated with the following processes: definition and simplification of complex problems, formulation of hypothesis, design and performance of experiments, control of variables, use of lab tools and equipment, making systematic observation, measuring, quantifying, representing experimental data, establishing relationships and connections among variables and phenomena based on the available evidence, inferring, making a scientific report and discussing and communicating results.

Additionally, it presents a situation where several science and mathematics concepts and procedures may be applied in a meaningful way (hydration, osmosis, health, differentiation and identification of variables, continuous magnitudes such as mass, volume and capacity, measurement of continuous magnitudes, equivalent magnitudes, units and values, additive and subtractive comparisons, data handling and representation and modelling of dynamic systems).

FINAL CONSIDERATION AND FUTURE IMPLICATIONS

National reports highlight the need to promote the use of new pedagogies to improve science and mathematic learning. In this setting, special attention should be paid to teacher education and teacher professional development, since teachers are the key players in educational reforms.

Research on effective learning and learning environments shows the positive effect of IBL on students' motivation, on the development of inquiry skills and on the promotion of conceptual understanding (Minner *et al*, 2010). Therefore, a classroom in which students use scientific inquiry to learn is one that resembles those that research has found the most effective for learning for understanding (National Research Council, 2000). However, an analysis of the Spanish context shows that IBL methodologies are not broadly used in our country.

Therefore, we have designed, implemented and refined an IBL activity for teacher initial training, as a way to promote the use of IBL methodologies in future teachers.

The opportunity to experience an IBL activity as students and to reflect on that as prospective educators could be a valuable tool, not only to improve their own science understanding and scientific process skills, but also, to develop interesting teaching competences for the application of IBL methodologies. The role of teachers in the implementation of IBL methodologies is a crucial factor affecting their success. Therefore, teacher training in IBL, entails drawing attention on how teachers should try to encourage reasoning rather the answer getting, build own students' previous knowledge and conceptions, and celebrate mistakes as opportunities for learning and improving, subtly showing students how they can work in profitable ways. It is also important to efficiently orientate group discussions, help students to make connection between ideas and highlight key ideas.

Taking into account the current interest in improving science education, the positive impact of IBL on science learning and the crucial role of teacher training and teacher professional development in the success of educational reforms, this pedagogical proposal may be considered as an interesting contribution to address these challenges.

NOTES

1. The Spanish Economic and Social Council, made up of employees' organizations, trade unions and other representatives of public interests, is a government advisory body, which means that its voice is heard in decision-making affecting the various sectors of Spanish society. The Spanish ESC studies and analyzes issues of concern to our society on its own initiative. Its annual memorandum has become an essential point of reference for understanding Spain's development and socioeconomic situation.

MATHEMATICAL AND SCIENTIFIC WELLBEING (M/SWB): BROADENING THE ORIGINAL CONSTRUCT

Philip C Clarkson1 and Wee Tiong Seah2
[1]Australian Catholic University
[2]Monash University

Abstract: For years it has been well known that there is an association between student affect and performance in school science and mathematics. However the intricacies of this association are still being teased out. In the current political environment when educational institutions are being explicitly asked to foster an environment that promotes student general wellbeing, this particular association takes on a new and significant meaning. But at the same time politicians and others in the community insist that narrowly defined cognitive performance is everything in mathematics and science (e.g. debate on PISA results). Within this old but still crucial area of research, we propose a new construct which we believe will move the debate forward. There are few tools with which teachers can gain insight into their students' wellbeing. In this theoretical paper we seek to broaden a construct, originally developed with mathematics in mind, for use in both science and mathematics classrooms. The construct should be useful in identifying and tracking students through a series of levels that will give an indication of how the students are coping emotionally in mathematics and science learning contexts. This construct grew out of our work on values in mathematics, combined with notions we found in the wellbeing area. We now draw on the science education research literature as well.

Keywords: Wellbeing; Science learning; Affect; Emotions; Values

PURPOSES AND PERSPECTIVES

Time was when the aim of learning mathematics was only perceived in cognitive terms. Later came the acceptance of the necessity to consider affective objectives, not just as an adjunct to the cognitive, but also as a 'driver' of mathematical learning, or non-learning (e.g. McLeod, 1992). A similar story is found in the science education literature where affect is now taken as a crucial issue for learners (Sinatra, 2005). Central to a deeper understanding of the role played by affective aspects in these learning contexts was the teasing out of what these aspects were. We and others have argued elsewhere that a pivotal aspect was the notion of values, although there have been difficulties translating this research into classroom action (Bishop, Gunstone, Clarke & Corrigan, 2006*;* Clarkson & Bishop*,* 2000). We now propose that a consideration of wellbeing offers a new way of recognizing the importance of the emotional aspects of, and the underlying values embedded in, mathematics and science learning.

"The literature does not provide a consistent definition or framework to measure wellbeing" (Ngyen, 2011, p.2). Nevertheless, notions of wellbeing in schools have mainly been envisaged as a generalist issue and often in terms of a healthy life (Catholic Education Office Melbourne, 2008; Lovat & Toomey, 2010). But for this notion to be a driving force for the betterment of students, wellbeing needs to be conceptualised as a core component of the school.

Hence for notions of wellbeing to impact directly on students, it needs to be conceptualised for the key subject areas and not left as a generalised feel good idea unattached to the core of what schools teach. These key subjects must include mathematics and science since the time students spend studying these subjects ranges from 25-40% of total school time. As well these subject areas are normally recognised by society as pivotal in students' education.

Interestingly Ngyen (2011) in reviewing the literature on wellbeing notes that teachers are in the better position to assess students' wellbeing, rather than rely on subjects' self-rating. The purpose of this theoretical paper is to introduce a new construct for teachers' use, dealing with the emotional state of students when they engage with mathematics or science; the *Mathematical / Scientific Wellbeing (M/SWB)* construct. This is the outcome of the first phase of an ongoing project. Following an introduction to the construct, we note references to a possible research agenda built around this construct and how it may impact on teacher education programs. We then comment on the responses of a small group of teachers to the construct, and conclude by reflecting on the significance of this work in progress.

DEVELOPING THE CONSTRUCT

A healthy sense of mathematical or scientific wellbeing should enable students to understand and apply mathematical and scientific concepts more effectively and in more sustainable ways, both in and beyond their school years. A positive wellbeing we argue is associated with the valuing of resilience, confidence, engagement, curiosity and efficiency; all values that are important not just for learning mathematics or science at a deep level, but also in living our daily lives. On the other hand, student disengagement in mathematics and science is an ongoing problem confronting most schools. Such disengagement would seem to be associated with a loss of wellbeing in the specific mathematical or scientific learning contexts. By the middle of elementary school it seems many students have become fixated on avoidance behavior towards these subjects. We came to believe that science and mathematics teachers could well do with a guide to help in gauging students' emotional responses. We also wondered if teachers were more aware of students' potential emotional responses, would they plan their lessons differently.

Our conception of the original *Mathematical Wellbeing* construct (MWB) was a series of stages through which we suggest students progress (Clarkson, Bishop, & Sear, 2010a). We summarise the main ideas of the original MWB in Table 1, but in that Table we have adapted it to speak to the science learning context as well (hence M/SWB). We have thought of the learner progressing through these stages as a state of wellbeing is consolidated. Age will be no definitive guide since we think that learners will be at different stages irrespective of age. Teachers may see aspects of cognitive development, but again this will not necessarily point to an M/SWB stage. Although we would generally expect this to be the case, we also know some students may well be developing cognitively, but still heartily dislike the subject. Alternatively, emotional growth may appear to be robust, but in fact it may be superficial, related only to some particular aspect of the learning situation, such as the behaviour of other learners. Clearly there is much to explore here.

As a student develops his/her M/SWB, we should see features of cognitive and affective objectives being satisfied at each stage. For example, a student who has been feeling a greater sense of M/SWB might be beginning to respond more positively to mathematical or scientific activities (that is, stage 2) and either knows or comprehends the demands inherent in these activities or tasks (cognitive domain), at the same time that the act of responding is reflective of affective educational objectives. At the same time, generally we would expect the interaction between M/SWB and growth in cognitive and affective objectives to feed on each other; given that a positive sense of wellbeing should stimulate self-confidence and foster enabling attitudes. Hence, if this interaction between M/SWB and cognitive/affective growth is mutually dependent and influential, then our ongoing quest to confront student dis-engagement (one of many manifestations of M/SWB) takes on new meanings, highlighting the importance of adopting a multi-prong approach involving cognitive, affective and emotional considerations.

Table 1: Modified stages of the construct ‘M/SWB’ (original in Clarkson, Bishop & Sear, 2010a)

Stage 1: Awareness and acceptance of mathematical and/or science activity:
The learner is aware of mathematics or science (M/S) as a non coherent collection of activities that is different in nature to other subjects. Although feeling comfortable in the context, has only a passive acceptance of such experiences and is disinclined to seek them out.
Stage 2: Positively responding to mathematical and/or science activity
M/S activity invokes a positive response. Indeed there is a welcoming of it and some pleasure in its pursuit and achievement, leading to feelings of self-confidence and positive self-esteem, which reinforces the acceptance and worthwhileness of such activity in general.
Stage 3: Valuing mathematical and/or science activity
The learner appreciates, enjoys and seeks out M/S activity, and people with whom these can be shared. Awareness grows of the human development of this knowledge, and of one’s place in the M/S scheme of things. The learner reaches acceptably high (to them) levels of competence.
Stage 4: Having an integrated and conscious value structure for mathematics and/or science
The learner values M/S and starts to appreciate future possibilities. This builds confidence in their level of skill, competence and judgments of their own strengths/weaknesses.
Stage 5: Independently competent and confident in mathematical and/or science activity
Now a fully independent actor on the M/S stage for their level. Can hold one’s own in arguments and is able to criticise other’s arguments from well-rehearsed M/S criteria.

We also suggest that students attain cognitive and affective educational objectives to different degrees at every stage of their mathematics learning and at any one time these are shaped by the student’s state of M/SWB. The higher order functioning in both the cognitive and affective realms involves the evaluation and finetuning of an individual’s value system, which in turn results in an increasingly integrated and conscious value system that regulates M/SWB. Such higher-order functioning constitutes a student’s life skill as he/she leaves school and contributes to the economic and social lives of the society. In other words, a more successful school education equips the student with this level of independence and wellbeing to deal with the many types of issues one comes across in life. At this level of personal growth, values and wellbeing are both stable enough to be regulating, but at the same time fluid enough to allow for adjustments as new insights and experiences 'makes one wiser'. This dynamic relationship between values and wellbeing has been investigated in contexts which are not directly related to mathematics and science education, but we suspect the same relationship will hold (e.g. Amin, Yusof & Haneef, 2006; Douglas, 2005; Eckersley, 2004).

The fostering of positive M/SWB needs to take into account how individual values have been – and continue to be – shaped and harnessed. For example, the successful cultivation of a student's valuing of *resilience* and *hard work* presents the student with opportunities to respond to intellectually challenging instances in his/her mathematics learning experience with a positive and enabling M/SWB. Alternatively, a student's valuing of *creativity* will likely support a more positive approach to novel problem situations, boosting his/her M/SWB in the process. On the other hand, one could picture a senior student who has developed over many years a relatively negative M/SWB. Her higher-order cognitive, affective and emotional functioning has shaped this outcome. But this outcome need not be regarded as a given that is fixed for life. By recognising this combination of cognitive, affective and emotional functioning, there is the potential for creative and purposeful designing of learning activities to stimulate such a student's independent critique and reviewing competence, to potentially redefine her M/SWB. This is highly complex, but at this level of functioning, the learner is well-equipped to evaluate cognitively, rationalising her emotional experience and decisions, in ways which characterise her being and wellbeing.

SPECULATION ON FURTHER EXTENSIONS AND INITIAL REACTIONS

In our original development of this construct we have suggested a research agenda (Clarkson, Bishop & Seah, 2010a) and how the construct may impact in teacher education (Clarkson, Seah & Bishop, 2010b) which we are also envisaging will apply to science. Here we briefly note some teachers' initial reactions. We asked eight teachers, after reading part of a chapter we had written outlining the MWB, to "Make some comments in relation to the MWB: in the way it is written, and why and how it could be used in your classroom." Each teacher wrote about one page of comments. Our analysis suggests that all of them saw value in such a construct and they said unequivocally that it would be used in their classrooms, with some suggesting that it could be reworded for students to also use. They noted "the sense" of interleaving the cognitive, affect and emotional aspects of learning into one construct, and thought exploring this with students would mean "the learning of mathematics (would be) more worthwhile in the eyes and minds of the learner." In effect the teachers thought that the use of the MWB construct would bring about a greater "sense of learning and engagement" for students well beyond the cognitive outcomes that seem to be the only valued outcomes for assessment. We have little doubt that we will receive similar feedback from teachers when we ask them about the M/SWB.

CONCLUSION

The M/SWB construct highlights the fundamental place of students' emotional development, an issue that has been gradually acknowledged, although only implicitly, in recent years within mathematics and science education. By building this construct we have tried to give depth to this issue and provide a possible way forward for addressing students' emotions when engaged with science and/or mathematics. We know that although many students master the procedures of mathematics and science, rarely does any sense of achievement ultimately remain. Rather it is their emotional dispositions (normally highly negative for mathematics, and for science 'it was sometimes fun but ultimately useless'), and the sense they made of the inherent mathematical and scientific values, that linger on through life (Clarkson, Bishop, Seah, & FitzSimons, 2001). We suggest that those students who positively responded to mathematical and science activities (M/SWB Stage 2 and further) are the ones who look back on their mathematics and science in school as engaging experiences. These are people who move into a long lasting sense of M/SWB, and hence can be much more productive within their society, and more constructive as they talk to their acquaintances and children about the good times of doing mathematics and science. Clearly there is much to be done in mathematics and science classrooms to reinvent these places of learning. A refocusing on values and emotions we believe will help to bring a greater sense of our students' M/SWB.

THE CHALLENGE OF IMPLEMENTING IBL CROSS-CULTURALLY AND CROSS-CURRICULARLY

Nina Cords[1], Robert Fischer[2], Amrita Prasad[2] and Manfred Euler[1]
[1]IPN Kiel, Germany,
[2]VUB Brussels, Belgium

Abstract: Facing the increasing lack of skilled workforce based on the declining interest of students in science and technology, the European Commission suggested a more appropriate implementation of natural sciences in the education systems. Therefore, several approaches have been made to improve the situation in school, among them the development of the Photonics Explorer (PEx), an educational kit funded by the EU. Since inquiry-based learning (IBL) is an accepted method to promote students' interest and motivation and improve the image of science and technology, the included didactic framework of the hands-on experiments in the kit is based on IBL. The aim of this study is to investigate the impact of the PEx on the students concerning interest, self efficacy and the image of physics.

In this paper we present selected results of the pilot study that has been conducted in Germany. It is shown that both the amount of IBL and being engaged with the PEx influences the students' image of physics. The field test will show to what extent the PEx has an impact on the students and reveal the differences of its educational value for each of the participating countries.

Keywords: Inquiry-based learning, experimental kit, optics, European project, educational material

BACKGROUND, FRAMEWORK AND PURPOSE

The lack of skilled workforce is an increasing concern for Europe's high-tech industries. One reason for this lack is the low interest of young people in science and engineering and the negative image of physics they already have in school (PISA Consortium, 2007; COM, 2009). As has been criticized by Hofstein and Lunetta (1982, 2004) students seldom experience real scientific methods and inquiring activities in school although experiments are an essential part of scientific work and experimental equipment used in class is mostly out-of-date (Tesch 2005). Many students consider physics boring and unattractive and therefore drop it as early as possible.

Inquiry-based learning (IBL) methods support the students to deal with real scientific work and raise certain research questions and also foster their scientific skills. They have a proven "efficacy at both primary and secondary levels in increasing children's and students' interest…" and additionally help students to develop a "critical thinking and reflection (…) to make meaning out of gathered evidence" (Csermely et al. 2007, p.2). However, teachers still seem to emphasise science concepts and facts rather than problem solving and critical thinking (Rennie, 2007). But even though IBL methods are seen as very effective way to achieve the goals of a knowledge based society and increase scientific literacy of its citizens, they are rarely implemented in classroom practice (Csermely, 2007).

The complexity of today's social, political and technological environment leads for many people to increasing troubles in understanding their surrounding world (Dubs, 2002). This is in line with the realization that the future competitiveness of a country strongly depends on the quality of education, especially in science and technology. The Rocard report even stated that "(...) among the population in general, the acquisition of skills that are becoming essential in all walks of life, in a society increasingly dependent on the use of knowledge, is also under increasing threat" (Csermely, 2007).

In order to link the goals of raising the interest of students in physics and to ensure scientific literacy among European's citizens, several approaches have been proposed. The EU funds numerous projects, among them the development of an educational kit to encourage students and teachers to extend scientific inquiry and to promote the interest of young people in science and technology in the field of photonics. This kit (Photonics Explorer, PEx) is an intra-curricular kit that will be handed out free-of-charge to teachers in Europe. The aim of the project is to promote the students' discovery and development of certain scientific and technical competencies, foster their open-mindedness for science and improve the image of physics in school.

In the development process of the PEx a group of experts in photonics, didactics and teachers from more than 10 countries were involved. The developed material contains robust and versatile components for hands-on work in small groups of two or three students to make sure everyone can be part of the investigation team. The provided worksheets of the PEx open with an every-day related topic that introduces the theme of the module to the students. The group is then asked to examine a given task and afterwards come up with its own ideas for an unknown problem. At the end, the whole class discusses its findings and sometimes presents the results in small groups. For each module a fact sheet is handed out that summarizes important aspects and facts to remember for the students.

The present paper sets focus on the question whether being actively engaged with the Photonics Explorer leads to an improvement of the image of physics.

RATIONALE

The survey determines among other things the effectiveness of the PEx on the improvement of the image of science, depending of the amount of IBL the students already have in their classes. In the present paper the results of the pilot study in Germany are shown and the challenges for the implementation of the PEx in 7 European countries are indicated.

METHODS

The image of physics has been acquired through a semantic differential based on the CAEB study (CAEB: An instrument of measuring connotative aspects of epistemological beliefs) by Stahl and Bromme (2007). Different adjective pairs have been chosen where the PEx is supposed to have an impact: important-unimportant; open-closed; exciting-boring; creative-uncreative; modern-old-fashioned; simple-complicated; fundamental-additional. The scale is referring on physics as a school subject. In order to specify the role of IBL, a latent class analysis was conducted to differentiate the students by the amount of IBL methods they have already experienced in their class.

A pilot study was conducted in March in Germany with 3 lower secondary schools classes (age 13-14) and with 3 upper secondary school classes (age 16-18). Overall, around 140 students have been participating in the pre-post-follow-up survey with paper and pencil. The students received the first questionnaire shortly before starting with the PEx in class (T1), one directly afterwards (T2) and one two months later (T3).

RESULTS

To show the impact of IBL methods in class on the students' image of physics, a latent class analysis was conducted. The best fit parameters were found for 3 different groups of students which are distinguished by the amount of IBL they already experienced in physics lesson so far (small, medium, high).
The use of the PEx in class leads for all students to significant changes in the aspect 'creative' but after two months they find physics as even more 'uncreative' as before starting with the PEx. Conducting experiments with the kit leads to physics lessons appearing 'simpler' which remains constant over the two months. In the follow-up-test the students stated that after finishing with the material in class the physics lesson changed significantly to 'boring' (data not shown).
The comparison of images of students with a high, medium resp. small amount of IBL methods in class reveals a different picture. As can be seen a significant difference already appears before starting with the PEx. The first group of students has a rather positive attitude towards physics (Fig. 1) as has the second group except for the aspects 'simple' and 'additional' (Fig. 2) while the third group has crossed more negative aspects throughout (data not shown).

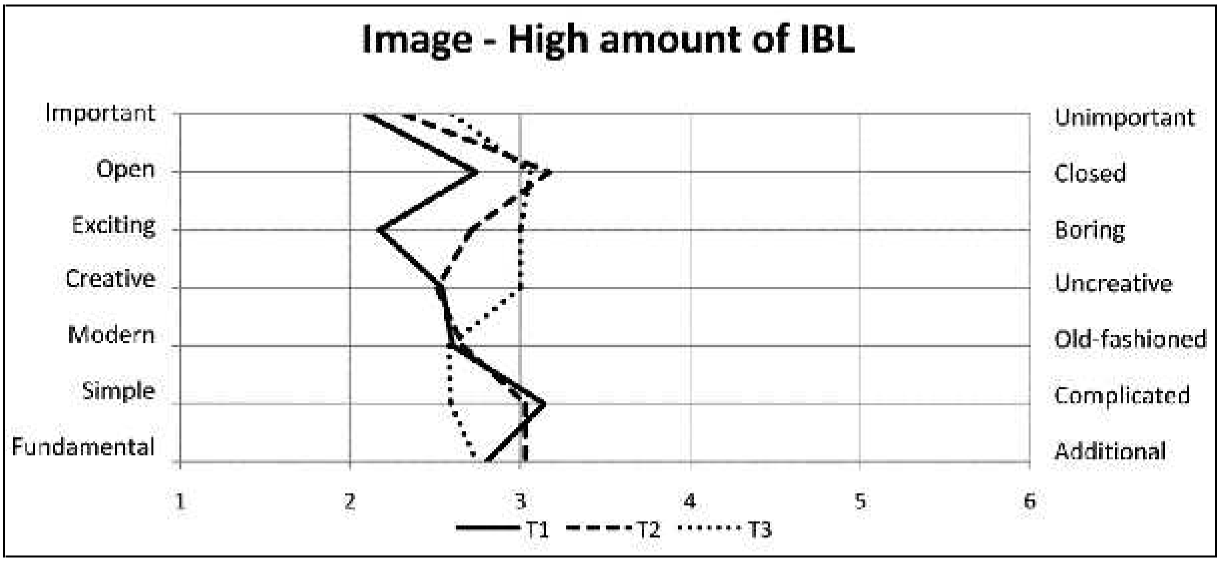

Fig. 1 Changes in the image of physics for students with a high amount of IBL in class

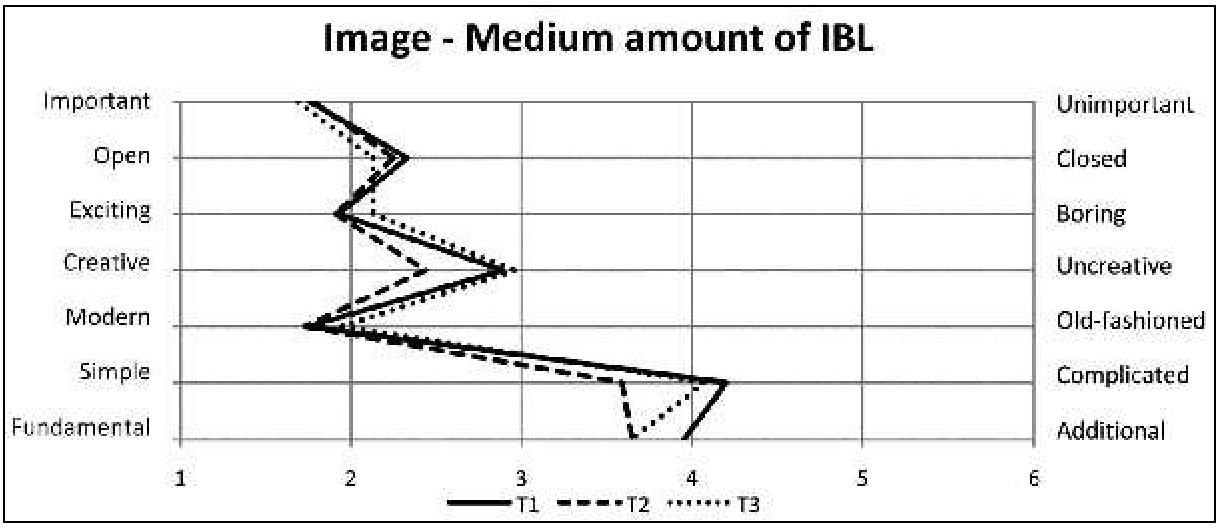

Fig. 2 Changes in the image of physics for students with a medium amount of IBL in class

For the group with high amount of IBL methods the treatment shows significant changes to ‘simpler’ but ‘more boring’. After the two months physics appears to be less ‘important’ and ‘simpler’ together with even more ‘boring’ than right after the treatment (see fig. 1). In the second group (medium amount) working with the PEx leads to the impression that physics is more ‘creative’ and ‘simpler’ which is not stable over the time of two months but decreases to the previous value. The usual physics lessons seem less attractive after working with the PEx, students experience physics as more ‘boring’ after two months (see fig. 2). On the contrary, the group of students with the small amount of IBL methods in class reveals no significant changes in all items (no data shown). In neither of the last two student groups does the PEx have an impact on the question of the importance of physics.

CONCLUSION, IMPLICATIONS AND CHALLENGE

The comparison of the two student groups suggests the assumption that using IBL methods in class lead to different images of physics in classrooms. Considering that the participating classes only tested one module out of four, we can expect greater changes in the different aspects of image due to the additional time the students are using the PEx. During the field test, the implementation of IBL methods will also be evaluated and would indicate a positive image of physics as could be seen on fig. 1 and fig. 2.

A big challenge that the project is facing in the test phase are the totally different curricula of the participating countries. As has been revealed by a re-analysis of the PISA study from 2006, the existing teaching-styles in the test countries reach from IBL methods with experiments on one side to teacher-centred on the other side (see fig. 3).

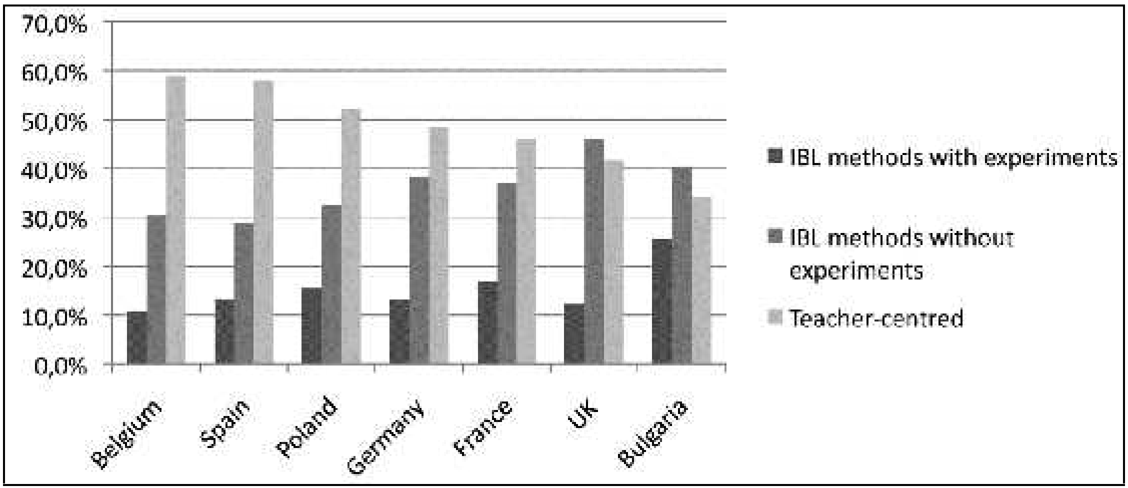

Fig. 3: Different teaching-styles in the participating countries of the project (Re-analysis of PISA 2006)

Being actively engaged with the PEx indicates a positive change on the students' image of physics. The students get the opportunity to attend the school topics in a different and rather autonomous and creative way. Therefore, the image changes to more 'creative' since it is not mere reproduction. They conduct experiments in small groups and get less instruction than in the usual lesson. Working hands-on is supposed to inseminate a different sense for experimenting und bring the students closer to the work of a real scientist.
The field test will show how the students learn in the other participating countries and how the implementation will work out in order to assess the impact and educational value of the PEx.

REPRESENTATION USE AND STRATEGY CHOICE IN PHYSICS PROBLEM SOLVING

Mieke De Cock[1]
[1]Department of Physics and Astronomy & LESEC, K.U.Leuven

Abstract: In this paper, we report on student success on a test item given in three different representational formats (verbal, pictorial and graphical), with isomorphic problem statements. We confirm results from recent papers where it is mentioned that students' problem solving competence varies (often strongly) with representational format.

Previous studies are complemented with a fine grained analysis of solution strategies. We can conclude that students use different problem solving strategies, depending on the representational format in which the (physics) problem is stated.

Keywords: physics, problem solving, representations, strategy choice

1 INTRODUCTION

Student competence with different representational formats gets lot of attention in recent research on physics and mathematics education. By 'representational format', we refer to the many different ways in which a particular problem or concept can be expressed, such as a graph, picture, free body diagram, formula …

Being skilled in using different representations and in coordinating multiple representations is highly valued in physics, both as a tool for understanding concepts (Kozma, 2003; McDermott, 2004) and as a means to facilitate problem solving (Dufresne, Gerace, & Leonard, 1997; Heller, Keith, & Anderson, 1992; Larkin, 1983; Reif, 1995; Van Heuvelen, 1995; Van Heuvelen, & Zou, 2001). Expert physics problem solvers are fluent in their use of different representations, can easily translate between them and can assess the usefulness of a particular representation in different situations. As it is a principal goal of most physics courses to produce adept problem solvers, a possible instructional aim might be to develop this representational fluency in physics students in order to benefit from using multiple representations.

There have been a number of studies that examined student performance in particular representations of physics problems, both inside and outside of Physics Education Research (PER) (see, e.g., Meltzer (2005) for a short overview). There also have been studies that compare student performance on problems that involve multiple representations to performance on problems that involve one single representation (Ainsworth, Bibby, & Wood, 1998; Mayer, 2003) and studies that investigate student skill in translating between representations (Kozma, 2003; Schnotz, & Bannert, 2003). A third group consists of studies in which students are explicitly taught to handle multiple representations of the same topic. Roosengrant, Etkina and Van Heuvelen (2006) give a short overview of recent literature on the use of representations in PER.

The line of research in which the current study fits, focuses on the relationship between student success and the representational format in which the problem is posed: how does the representation in which the problem is formulated affect student performance and solution strategy (Koedinger, & Nathan, 2004; Kohl, and Finkelstein, 2005; Meltzer, 2005)? Answering this question is not only interesting from a theoretical point of view, but also from an instructional perspective. If it turns out that a particular representation is more suited to solve a specific kind of problems, it is important to train students not only in working with different representations and translating between them, but also to teach them how to choose adaptively an appropriate representation.

Both in the work of Meltzer (2005) and of Kohl and Finkelstein (2005) student performances on problems in different representational formats (verbal, mathematical, graphical and pictorial or diagrammatical) were compared. Both author groups conclude that student performance on nearly isomorphic problems (quiz and homework) stated in different representations, varies significantly. When there was a performance difference between two formats, the ‘mathematical’ format often was one of the formats involved. Results show that on average, students were more successful in the mathematical format (or a format in which a numerical calculation can lead to the solution), which is consistent with the idea that first-year students are more comfortable with ’plug ’n chug’ types of problems than with conceptual questions (Mazur, 1996). Kohl and Finkelstein broadened their investigation by giving a group of students a choice of formats (before they read the problem), and by comparing the results of students in the choice condition to the results of students that were randomly assigned one of the four representational formats. It was found that allowing students to choose did not consistently increase or decrease success relative to the control groups, but that the effect varied strongly both across topic and across representation.

In this study, we use items mentioned in the paper by Kohl and Finkelstein (2005) as a starting point to replicate part of the study. Student answers are studied and results are compared to the outcomes mentioned by those authors. Moreover, we broaden their investigation by asking the students for an explication and we extended the analysis by studying the written justifications in detail. These written explanations allow us to study the physical concepts and the problem solving strategies that students use.

The main research questions thus are:

1. Do students perform differently when solving a physics problem formulated in different representational formats?
2. How are the solution strategies of students affected by the representation used in the problem statement? Do students use different solution strategies in different representations?

2 METHOD

The study was conducted in a large-enrollment (± 200 students) introductory physics class. Students are typically first year students, all taking the mandatory course as part of the pharmaceutical science program. Students’ math skills are quite varied. The course in this study was a first semester class in the fall of 2009. The format of the course is mostly traditional, with some in-lecture concept tests. Students have two two-hour lectures per week, and meet for three hours each week in a traditional recitation session. Besides the lectures and the recitation sessions, there are three three-hour lab sessions. Students’ grades were based on exams, labs and homework assignments. Homework problems consisted mainly of qualitative conceptual problems (online).

Here, we report on student responses to a selected mid-term exam question: one research item was included in the questions of a mid-term test. Participation in the test was free and test results did not count for the students’ final grade. The representational format in which the research item was formulated, was randomly varied between students. The test item we used to study representational competence is a translation of the verbal, graphical and pictorial version of the question on energy and energy transformation developed by Kohl and Finkelstein (2005) and is shown in Figure 1. Because the main focus of the test was on conceptual understanding, it was decided not to use the mathematical format, where the original item was explicitly asking to compute a (numerical) speed.

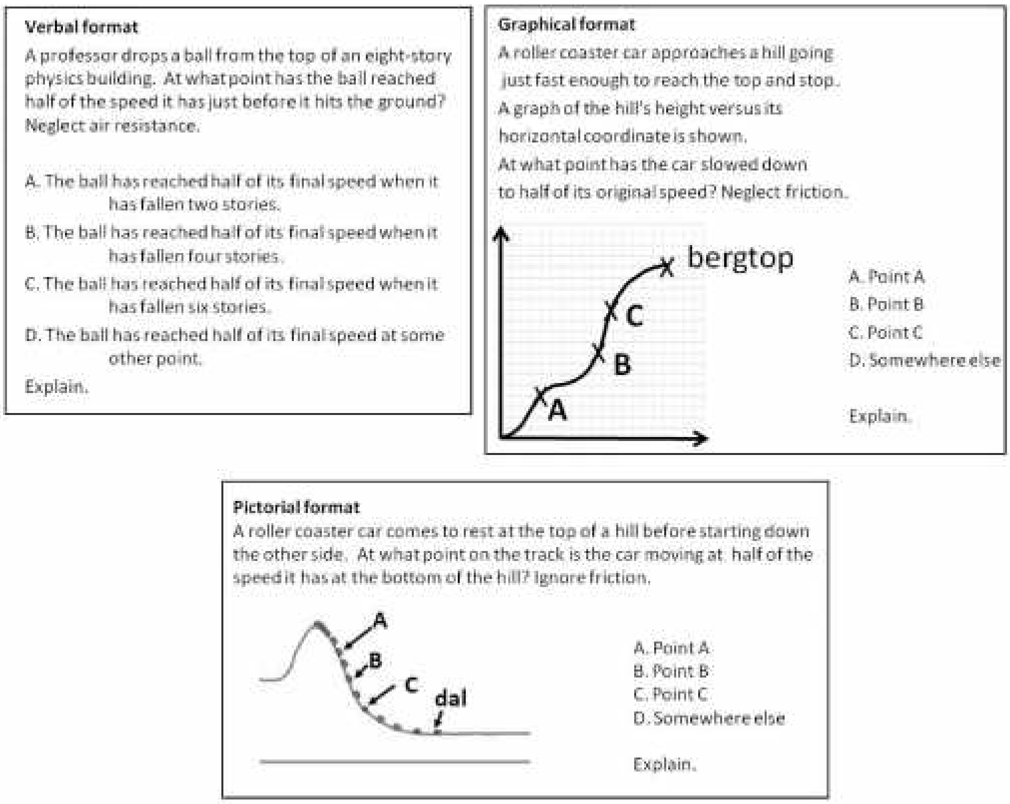

Figure 1: Verbal, graphical and pictorial format of the test item, adapted from Kohl and Finkelstein (2005)

As mentioned in the original article (Kohl, & Finkelstein, 2005), these problems are meant to be isomorphic from format to format, with the answers and distracters mapping from one format to the other. By isomorphic, the authors mean isomorphic from the point of view of a physicist. The test items that we used differ from the original ones in the sense that we do ask the students to explain their choice. Both the choices of the alternatives and the written explanations are studied in detail.

When studying the items as pure multiple choice questions, we only take into account the alternative picked by the students, without considering the explanations. This means that also choosing the correct alternative with an erroneous reasoning or without an explication is counted as correct. However, when taking into account explanations, an argument is only evaluated as ’correct’ if it consists of a correct physics reasoning and a correct conclusion. An incorrect physics reasoning or a mainly correct argument but with a wrong conclusion is considered incorrect. Answers without justification are categorized as incorrect.

3 RESULTS

In this section, we compare student performances on the test problem in different representational formats and focus on the solution strategy that students choose in the different formats.

Performance in different representational formats

In Table 1, the fraction of students that answered the test item correctly is shown, not taking into account their explanations. The number of students answering the question in the particular formats is given in parentheses.

Total number of students:189	Verbal (N=62)	Gaphical (N=64)	Pictorial (N=63)
Correct alternative	0.44	0.28	0.33
Correct alternative + correct justification	0.40	0.06	0.13

Table 1: Fraction of students answering correctly, broken down by representational format

All statistical significance tests involving student success rates are two-tailed binomial z-tests. We consider a difference with $p > 0.10$ as not significant, p between 0.10 and 0.05 marginally significant, p between 0.05 and 0.01 significant, and $p < 0.01$ highly significant.

When considering only the answer options (a-b-c-d) and not the explanations (Table 1), the difference between the verbal and graphical format is marginally significant (p=0.07), whereas the other differences are not significant. This is in line with the results in the original paper (Kohl, & Finkelstein, 2005).

However, when taking into account the explanations given by the students, results look quite different. Table 1 also shows the fraction of students choosing the right alternative, AND giving a correct explanation for their choice. When comparing these results, we find that the differences between verbal and graphical format and between verbal and pictorial format are highly significant (p=0.0006 and p=0.001 respectively), whereas graphical and pictorial format do not differ significantly from each other. It is almost immediately clear that the fractions of correct answers with or without taking into account the explications, do not differ significantly for the verbal format (p=0.72), but the difference is highly significant for the pictorial (p=0.006) and the graphical format (p=0.001).

Solution strategy in different representational formats

As we did not expect these results, we looked in detail at the students' explanations in order to find out how these differences can be explained. We found that students justify their answers differently in the different (representational) formats. Some explanations are based on kinematics, some on conservation of energy or on a linear reasoning. There also were arguments which are strongly tied to the visual information in the representation. In what follows, different solution strategies are discussed.

Conservation of energy versus kinematics
In Table 2, the fractions of answers using kinematics and conservation of energy (not necessarily in a correct way) are shown for the different formats.

Total number of students:189	Verbal (N=62)	Gaphical (N=64)	Pictorial (N=63)
Fraction of explications using kinematics	0.56	0.22	0.14
Fraction of explications using energy conservation	0.23	0.34	0.43

Table 2: Fraction of answers with justification based on kinematics and conservation of energy in different representational formats

The difference between fractions of answers using kinematics in the verbal and graphical format is highly significant (p=0.00006), as is the difference between the verbal and pictorial format (p=0.00006). The difference between the graphical and pictorial format is not significant.

When comparing the fractions of answers based on conservation of energy, the difference between verbal and pictorial format turns out to be significant (p=0.016), while the other differences are not significant.

When looking within the different formats, it turns out that the fraction of students using a kinematics argument differs significantly from the fraction of students writing an explanation based on conservation of energy for the verbal (p=0.0001) and pictorial format (p=0.0004). However, for the graphical format, the difference between the fractions is not significant. In the verbal format, more students solved the problem using kinematics than using conservation of energy, whereas for both other formats, more justifications are based on energy conservation. Out of the 25 students that solved the item correctly in the verbal representation, 18 of them justified their answer using kinematics, while only 6 students based their argumentation on conservation of energy. One student used a correct combination of conservation of energy and kinematics to explain his answer. In the graphical and pictorial format, none of the explications based on kinematics is correct. The correct explanations in these formats are all based on conservation of energy.

These results suggest that the different formats are not completely isomorphic: the verbal format is one dimensional and as such leaves the possibility to solve the problem using kinematics. This is not the case for the other two formats, where the two dimensional (2D) character prevents the easy use of kinematics. More interestingly, the results also suggest that, if possible, students are more likely to apply kinematics than to apply conservation of energy. However, the data for the graphical and pictorial format seem to suggest that students are aware of the difficulty of the use of kinematics in these situations: a smaller fraction of students uses a kinematics argument in these situations than in the verbal formulation.

Conservation of energy

In a next step, we studied the 'conservation of energy answers' in detail. We found that a lot of students had trouble to apply the principle of conservation of energy correctly. In Table 3, we present the number of students using a correct conservation of energy explication.

	Verbal (N=16)	Gaphical (N=26)	Pictorial (N=21)
Correct application of energy conservation	0.43	0.18	0.30

Table 3: Distribution of answers using a correct argument based on conservation of energy

Although, from Table 2, we see that the fraction of students using a conservation of energy argument does not differ between formats, Table 3 shows that in these arguments, more errors are made in the graphical and pictorial format, compared to the verbal format.

Linear reasoning

An interesting distracter is answer *b* in each of the formats. This alternative could correspond to a 'linear reasoning': 'half of the final speed is reached halfway'. In mathematics education, a vast amount of research has shown that students have a strong tendency to apply linear or proportional models anywhere, even in situations where they are not applicable (De Bock, Vandooren, Janssens, & Verschaffel, 2007). In Table 4, the fraction of linear answers (i.e., the fraction of students answering alternative *b*) is given for the different formats.

Total number of students:189	Verbal (N=62)	Gaphical (N=64)	Pictorial (N=63)
Fraction of linear answers	0.13	0.42	0.33

Table 4: Fraction of students choosing the linear alternative in the different representational formats

It turns out that the difference between verbal and graphical and verbal and pictorial format is highly significant (p=0.0002, and p=0.007 respectively). The difference between graphical and pictorial format is not significant (p=0.3).

Analysing the explanations of students picking alternative *b*, shows that not all of them refer to a linear reasoning (e.g., stating 'the car will have half of its final speed halfway'). On the contrary, most of them use (wrong) energy or kinematics arguments. In the verbal format, 4 (out of 8) students refer explicitly to a linear argument to pick alternative *b*. In the graphical format, 7 out 27 use a linear reasoning, while in the pictorial question, only 2 students (out of 21) use this kind of argument.

Representation dependent cueing
From the above, it is clear that both performance and problem solving strategy used by students differ between representational formats. Conservation of energy, kinematics and linear reasoning are already mentioned, but another class of arguments seems to be strongly related to the representational format: quite a few students explain their choice by referring to the slope or tangent in the picture or graph in the question, thereby mistaking the position (time)-graph with the picture of the hill or the vertical direction (horizontal direction)-graph. 7 students (11%) make this mistake in the pictorial format, 10 (16%) in the graphical but, of course, none in the verbal version.

4 DISCUSSION AND CONCLUSION

In this study, we did investigate the role of representational format in student performance when solving physics problems. The work of Meltzer (2005) and Kohl and Finkelstein (2005) indicates that student performance can vary strongly with the representation used in the formulation of a question. By asking students for detailed explanations, we gained more insight in these differences. Kohl and Finkelstein suggest that performance differences depend on a number of things, including student expectations, prior knowledge, metacognitive skills, and the specific contextual features of the problem and the representations. Moreover, they argue that different problem representations might prompt different solution strategies.

Only one test item is included in this study, but as we asked students to explain their choice, we could study the strategies used by the students. This detailed study confirmed the performance difference across representations and revealed that these differences can - to a large extent - be explained by the fact that students use solution strategies based on different physics ideas to explain their answers in the different formats. The problem formulation of the verbal format allows both the use of 1D kinematics and conservation of energy to solve it. This is not the case in the graphical and pictorial formats, where students preferably use conservation of energy to argue their choice. Detailed analysis of the data do confirm that students use the 1D kinematics often in the verbal format and that most of the correct answers are based on a kinematics argument. The number of correct explications based on conservation of energy is surprisingly small, in all three formats.

With quite some students arguing based on the slope in the picture or graph, we found evidence consistent with the idea that specific, micro-level features of a representation can prompt students to a particular solution strategy/argument, as is suggested in Kohl and Finkelstein (2005).

While this study did not have the intention to develop or test new instructional materials or techniques, we can speculate as to the instructional implications of the results. We have found another example in which student performance was significantly affected by which representation was used, and that impact could be tied to representation-dependent problem features that either cued an answer directly or changed the students' overall strategy. Instructor awareness of this sensitivity to representation would likely to be productive.

WORLDVIEWS TO THE CONCEPT OF EVOLUTION AMONG STUDENTS IN AN INITIAL TEACHER TRAINING COURSE

Luís Fernando Marques Dorvillé[1] and Sandra Escovedo Selles[2]

Abstract: The present work shows the close relation between evolution rejection and protestant fundamentalism in students from a teacher training course in Brazil, together with a discussion on the best approaches to deal with this situation. The imposition of science explanations was rejected together with those from relativistic interpretations of science.

Keywords: Biology Teaching; Science Teaching; Evolution; Creationism; Teacher Training.

BACKGROUND, FRAMEWORK AND PURPOSE

The debate opposing Science and Religion, although still held by some authors, has proved for many others to be misplaced and religious thoughts apparently still have an important place to take in the lives of many of the contemporary human beings, many times side by side with the acceptance of the most recent scientific developments and concepts. However, this does not mean, as proposed by Gould (1999), that Religion and Science peacefully took separate places in the minds of everyone as Non- Overlapping Magisteria.

Quite the contrary, the last century has witnessed the emergence of a typical modern phenomenon, named religious fundamentalism, which in the western countries had its major source in the United States of America in some conservative protestant denominations (Numbers, 2006). More directly related to Biology and Science teaching is the “scientific” facet of this movement, that albeit its religious motivations, presented itself initially as “scientific creationism” and lately was renamed by its followers as “intelligent design” (Alters & Nelson, 2002). This movement deeply opposes many of the basic ideas that form the core of the modern evolutionary synthesis and although initially restricted mainly to the United States (Scott, 2006), began to spread to other western countries especially through the activity of religious institutions.

As stated by Numbers (2006), nowhere in South America antievolutionists have made deeper developments than in Brazil, where this issue has been assuming an escalating importance and has reached its climax on March 2002, when the governor of the State of Rio de Janeiro, a Presbyterian politician supported to a great extent by the evangelicals, sanctioned the law that authorized the teaching of a new subject, “Religion”, in the public schools of the State. At the time the governor took the chance to declare her support for the biblical creationism and rebuffed the idea of biological evolution of the species.

The study herein reported was carried out in an initial teacher training program in Biological Sciences in the Universidade do Estado do Rio de Janeiro (UERJ) and is located in a municipality in the outskirts of the metropolitan region of Rio de Janeiro, Brazil.

This work aims to investigate the possible association between the religious affiliations of forthcoming Biology and Science teachers and their reactions to biological concepts related to biological evolution and its consequences. The research questions of this paper are: 1 - Is there any association between religious affiliation and rejection or resistance to the concepts related to biological evolution?; 2 - If such association is found, could it be more intense in some religions than in others? Which ones?; 3 - Which best strategies could be employed by forthcoming teachers of Biology and Science when dealing with this sort of conflicts? Which ones should not be encouraged?

METHODOLOGY

A survey of eleven questions/statements (eight dealing directly with biological concepts) was applied to all the students which agreed to participate in this study and that were following different periods in the teacher training program in Biological Sciences at the UERJ in the beginning of 2004. A total amount of 245 surveys were collected. Recorded interviews with five students from different religious affiliations were also included to complete the empirical basis of the research.

RESULTS

In almost all the biological questions of the survey, the highest percentages of disagreement between the evolutionary concepts and the worldview of the students came from those from a strong protestant background. In the first question, for instance, while 91.7% of Catholics agreed with the idea of kinship between different living beings, followed by 87.5% Non Religious students, and 84.2% of Spiritualists, only 76.5% of the Protestants did so. Besides that, among those that responded affirmatively to this question 50.91% of Catholics employed evolutionary arguments, followed by 45.83% non-religious students, and 42.11% of Spiritualists (second question). The lowest numbers (33.33%) came from the Protestants in which the typological arguments reached their highest level. The lowest percentages were also found among Protestants about the following statements: all living beings descend from a single form of life (third question, 18.4%); the human species came from another different species (fourth question, 38.5%); all species change throughout time (fifth question, 45.1%). Moreover, this was the only religious group to predominantly reject both third and fourth questions. Their answers were also quite unique since 35.29% chose the option “there is no proof that living beings change originating different ones throughout time” in the fifth question. On the other hand, their responses reached the highest levels in the following statements/questions: our species is the only rational one. Is there is a reason for that? (ninth question, 50.0% found a religious reason); what is the definition of evolution? (tenth question, 34.62% considered it only a hypothesis); have other species appeared after the origin of humans? (eleventh question, 46.15% answered negatively).

The only exception regarding the uniqueness of protestant responses to biological statements came from the eighth question, which inquired “what does it mean for a living being to be more evolved than other one?”. In all religious groups the most common answer was “more adapted/specialized”, revealing both a static view of the environment and a unidirectional conception of the evolutionary process, which misunderstands evolution as a process of species improvement (Protestants – 55.77%; Catholics – 46.55%; Spiritualists – 52.63%, and Non-Religious – 50.00%). In the second place, regardless of religious groups, came the answer that best expresses the evolutionary paradigm, in which the most evolved species are those “that suffered more changes throughout time” (Catholics – 34.38%; Protestants - 23.08%; Non-religious – 22.73%, and Spiritualists - 15.79%).

DISCUSSION, CONCLUSIONS, AND IMPLICATIONS

The results herein presented reveal a significant amount of rejection and resistance among a large group of students, not to a secondary peripheral area of Biology but to the central tenets that established this knowledge as science in its contemporary form in the first half of the 20th century (SMOCOVITIS, 1992). This rejection is by no means the result of cognitive difficulties or related to the shock of getting acquainted with a different and strange language held by the scientific community, since many of the students seem to master properly the major biological concepts they were taught and do well in most of the exams. Similar results have also been found in Brazil for future Biology teaching students by Sepúlveda & El-Hani (2010), for graduating students from different areas by Souza *et al.* (2009), for Secondary Education teachers (Tidon & Levontin, 2004), and for the pupils from elementary school by Fonseca (2008), showing that this is by no means an isolated situation and that forthcoming Biology and Science teachers should be aware of it.

The results of this work remark the importance of developing teaching strategies adequate to deal with this situation, one which surely takes into account the importance of "contextual constructivism", a term coined by Cobern (1994), which according to him would be a cultural constructivist approach. This view regards the learning process as a much more complex task than only a personal activity, always taking place in a social context.

In this way, we agree with McKeachie *et al.* (2002) that teaching strategies should involve not only the transmission of correct and up to date scientific knowledge but also need to create cognitive dissonance with some of the creationist thoughts so dogmatically held by some of these students. This dissonance should not be presented as an antagonist relation but fairly presented as worldview conflicts about certain issues to the students, remarking about the different fields in which they were supposed to act. Therefore, our main goal should be, as addressed by Pigliucci (2007), to move these students out of their comfort zones, opening their ideas to situations in which they are subjected to scrutiny and debate with other views. In this way, we should aim to foster situations that enhance the chance of argumentation by these students and that allow their interaction with new and unusual situations to take place. In this learning process the issues covered during the course are not important in themselves but the way they are used is central for the success of this methodology. However, this said, it is clear that some of them are more likely than others to promote heuristic dissonances. Various authors have suggested more promising subjects in Biology to deal with the teaching of evolution, and all of them have been proven useful in our classrooms.

Gregg *et al.* (2003), for instance, stressed out arguments based on the molecular level, such as the common structure of DNA, of the processes of protein synthesis, the presence of metabolic pathways identical in all living beings and the universality of the genetic code, among others, with the appeal not only from the logical arguments but also from the symbolic power carried nowadays by everything related to the structures and processes at the molecular level. Antolin & Herbers (2001) presented evidences of evolution through situations related to current issues from Medicine (development of microorganism strains resistant to antibiotics), Agriculture (selective breeding and the generation of different varieties of animals and plants), and Biotechnology (genetically modified organisms). Images of transitional fossils - especially those that do not clearly fit into those basic kinds or types found in present animals - , together with similar embryonic developmental stages in complete different adult animals, have also posed challenging questions to these students.

Also, as mentioned by Pigliucci (2007), it is important to follow the trajectory of those students that initially had a hostile attitude towards evolutionary concepts and later have managed to overcome these conflicts. The careful examination of their mediating strategies may provide important clues about what might work or not, always bearing in mind that although individuals have different stories, some general patterns and tendencies might emerge. Accordingly, when teaching evolution later, one of our former creationist students chose to deal with the most problematic issues later, not as a way to hide them, but in order to provide their pupils first with the basic knowledge necessary to better understand the process. Without this, their ability to fully comprehend all the arguments and inconsistencies present in the discussion would be seriously compromised and rejection would follow immediately.

This approach should be accomplished assuring the students that this is by no means a debate about Science *versus* Religion and so they must not be discouraged about their religious beliefs, therefore avoiding some aspects of science teaching criticized by Aikenhead (2002). This author has emphasized that in many instances science teaching acts as a dominating enterprise in which all students are exposed to a single culture disguised as neutral knowledge transmission. Otherwise, the same dogmatic attitude is strongly supported by most creationists in the opposite direction, and so should be answered likewise, that is, confronted with the power of debate and exploring the heuristic value of conflicts. These students come to the university bearing, at different degrees, a number of several dogmatic truths, most of them linked to the religious matrix they follow. Any other way of thinking presented to them that also work based on absolute certainties will surely be in disadvantage with their religious views. Therefore, the teaching of any dogmatic version of science, besides incurring in serious epistemological misinterpretations of the scientific activity, is also a weak and innocuous didactic strategy when dealing with these students.

We strongly believe that the best strategy is to present science as a field of questioning and discovery that almost always is tentative. This is a way of thinking that most of these students are unaware and that do not struggle for space directly with their religious views. For many of them, change and instability have necessarily a negative connotation and hence we should emphasize the importance of explanations that are not based on stability, but that rather work through critical revision, involving advances and retreats, disputes, loss of data and its recovery, besides having a generous space for stochastic phenomena. The teaching of this relentless movement is able to foster in these students the conditions necessary to better welcome some of the scientific explanations or at least debate them with consistent arguments, going beyond immediate rejection. Thus, the presence in our curriculum of a discipline about History and Philosophy of Science has helped us in teaching the nature of science, their limits and possibilities, allowing these students to recognize which explanations are parts of the scientific endeavor and which are not. The importance of the different contexts in which these explanations are applicable reveals its importance and religious explanations like creationism and intelligent design do not belong to the scientific field.

Finally, in a nutshell, our defense of a cultural constructivist approach of teaching science and its changeable nature should not be confused with some relativistic interpretations of the reality. Some of them consider any explanation of reality held by any group of people as valid as any other (including the scientific ones) based on the impossibility of seeing the real world as it is. This approach, very popular in some trendy academic circles, have been craftily framed by religious fundamentalists throughout the world in order to promote their agendas, creationism included (NANDA, 2003). Our viewpoint is based on the critical realism defended by authors like Chalmers (1993) and on our understanding that the debate between different cultures is not based on their essentialistic nature, rather considering them to be engaged under processes of multiple influence. Therefore, since knowledge is socially constructed, the best way to respect the members of a particular culture should be neither impose another foreign view over them nor isolate them from any debate and exchange with other experiences and points of view. This is especially true if the members of this group have cultural views that are based on dogmatic religious visions and are not living remotely isolated but in the outskirts of modern cities with an involuntary limited access to different sources of information.

FORCE DYNAMIC GESTALT OF NATURAL PHENOMENA: TEACHING THE CONCEPT OF ENERGY

Hans U. Fuchs[1], Federico Corni[2], Enrico Giliberti[2], Cristina Mariani[2]

Abstract: Modern cognitive science in general and cognitive linguistics in particular teach us about basic figurative structures of the human mind which are used to conceptualize natural, psychological, and social phenomena and processes. These figures of thought are based on schematic structures that develop early in the life of a child. We have identified a structure, the Force Dynamic Gestalt, which underlies both everyday language and reasoning and the formal science of physics. If teachers learn to make use of these figurative structures, they are in a position to produce well-crafted narratives with which they can confidently teach other- wise complex and formal subjects. We demonstrate how to use the approach for developing the energy concept in primary school. The method lends itself well to a deliberate movement from the affective and qualitative to the logical and quantitative, and to the use of role games, stories, outdoor activities, laboratory work, drawings, writings etc. Linguistic and graphical tools will be described that make this approach not only simple but also natural.

Keywords: Cognitive linguistics, image schemas, metaphors, force dynamic gestalt, energy.

1. INTRODUCTION

Many studies have identified "misconceptions" in pupils' understanding of the energy con- cept. Some researchers (Solomon, 1983; Watts, 1983; Duit, 1984; Trumper, 1990, 1991; Log- man et al., 2010) have created categories and conceptual frameworks for describing children's ideas concerning energy. Krugher et al. (1992) found that teachers often share these same na- ive ideas. Generally, authors find that learning the concept of energy has little lasting effect on students (Finegold and Trumper, 1989; Trumper, 1990a; Kruger et al., 1992). A possible strategy for improvement is to start with what children know and then modify their know- ledge. Ogborn (Ogborn, 1990; Boohan et al, 2001) notes that "we, like other animals, are built to pay attention to differences." He suggests that in developing the energy concept, we should make use of children's spontaneous thought by paying attention to perceived differences that drive processes.

Here, we present an extended and unified analysis of deep-rooted thought processes and show how they may be employed in teaching the energy concept. We shall demonstrate how hu- mans describe *generalized forces* such as pain, justice, imagination, light, heat, electricity, and many others. We commonly use image schemas that are projected metaphorically onto the ge- stalt of a phenomenon. The three most important schemas are those related to *intensity*, *quan- tity*, and *force* or *power*. Note that we do not use the term *force* in the sense of force in New- ton’s laws. Nor do we use the word *power* in terms of the physical concept power (as in the rate at which energy is released in a process). However, we will *associate* the schema of force or power with energy when creating theories of physical processes.

2. ENERGY AND THE FORCE DYNAMIC GESTALT

When children and adults speak spontaneously about physical processes, they do so in a form that reveals what we call the *Force Dynamic Gestalt* (FDG; Fuchs, 2007, 2010a). Cognitive linguistics (Lakoff and Johnson, 1999; Johnson, 1987; Talmy, 2000) shows that we base understanding upon certain schematic figures of thought that show up in language. Three of the most important are used to conceptualize natural, emotional, and social phenomena ranging from heat and light to pain and justice. The three schemas that form the basis of the FDG are quantity (size), quality (intensity and its differences), and force or power (see Fig. 1). (There are additional schemas that structure our understanding of forces such as balance, resistance, container, etc., which have been identified by Talmy (2000) in his theory of force dynamic structures of our language of causation.) These schemas are projected metaphorically onto a phenomenon in question (Fig. 2). We say, for example, (1) that there is heat in a room and that it can flow (metaphor: heat is a fluid substance), (2) that heat becomes more intense or that the temperature rises (metaphor: heat is a thermal landscape in which bodies move up and down or along a scale of hotness), and (3) that heat can be the cause of other processes (metaphor: heat is a powerful agent).

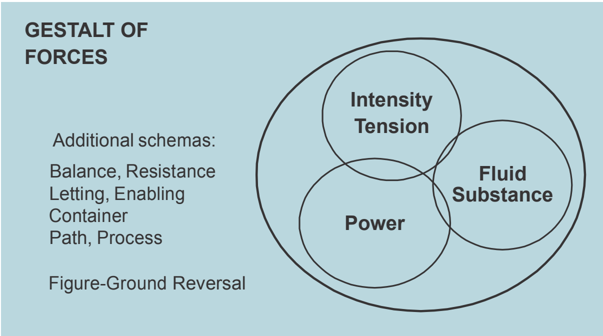

Figure 1. Schemas making up our conceptualization of a gestalt of forces (the Force Dynamic Gestalt, FDG).

Different phenomena (forces such as heat or electricity or others) are structured metaphorically using the same set of schemas (Fig. 2). This makes phenomena that do not have anything in common objectively similar to the human mind. As a result we see them as analogous and we can apply analogical reasoning. Note that metaphors are uni-directional projections whereas analogies are bi-directional.

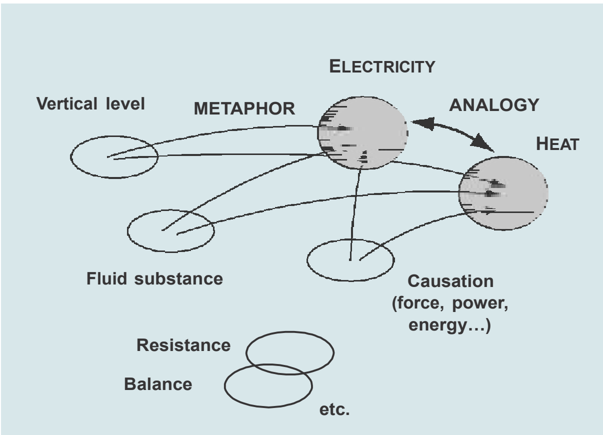

Figure 2. Metaphoric projection of schemas onto the target domain of a phenomenon. If the same schemas are used to metaphorically structure different targets, these domains become similar to the human mind which allows for analogical reasoning to be used.

We consider the third of these schematic aspects—*force* or *power*—the source of our notions of *energy*. Note that we do not have to use the word energy when speaking about it. This is certainly true for children, but also for adults. If we want to understand the energy principle as growing from the aspect of the power of a natural phenomenon, we need to learn about the schemas of fluid substance, (vertical) scale and its differences, and direct manipulation. We need to understand how the three are distinct and related (for example, the power of heat is proportional to a quantity of heat falling through a difference of temperatures, and proportional to this difference; this is Sadi Carnot's explanation of the power of heat in heat engines, see Fig. 3 and Fuchs, 2010b). This goal can be best achieved in early education by making use of well crafted stories that employ the power of schematic structures identified in narrative thought (Fuchs, 2010a).

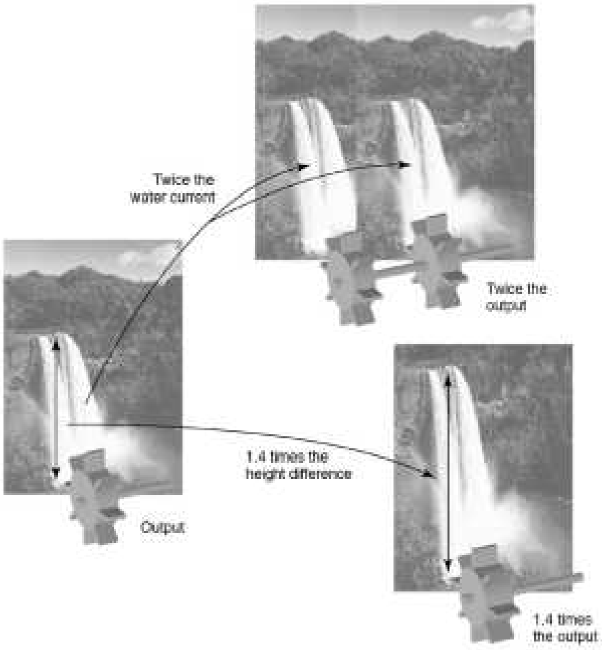

Figure 3. Sadi Carnot's image of the power of heat engines in analogy to the power of a waterfall.

It has been demonstrated that the conceptualizations used in macroscopic physics follow the structure of the FDG (Fuchs, 2007, 2010b). Processes are described as the result of the storage, flow, and production of fluid-like quantities (amount of substance, momentum, charge, entropy…). Transports, production, and storage are related to differences of intensive quantities (chemical potential, velocity, electric potential, temperature…), and the power of a process is determined as the product of current and potential difference. Therefore, we can construct the scientific concept of energy starting in early childhood if we nurture these everyday figurative conceptualizations that are, at the same time, the schematic structures of a formal science. By stressing the utility of every-day thought we do not mean to oversimplify a difficult subject, or to adopt a naïve view of understanding of nature. Rather, we want to let human thought evolve naturally using its own strength. Clearly, a teacher-training program based on the concept of the FDG can further this goal.

3. INTRODUCING TEACHERS TO THE ENERGY CONCEPT

Teachers have to be comfortable with their understanding of a principle before they can teach it confidently. We believe that if they know the foundations of a child's language concerning natural processes—which are the foundations of their own language as well—they will be in a position to be self-confident and creative in their teaching.

Here is an example of the use of everyday language that reflects the FDG and shows how the energy concept can be developed. Consider a watermill using the fall of water to grind flour. The story starts with a tension in the form of a height difference through which water can fall. This drives the millwheel and the millstone. The power of the water is quantified in terms of amount of water and height difference. The millstone (runner stone) turns relative to the stationary bedstone and the wheat between. Because of friction, the runner stone communicates its spin to the stationary stone and from there to the earth. At the same time, wheat is ground and some heat produced. Note that there is a tension, a speed difference, between the two stones, and we can introduce the notion of power of the rotational process. In summary, the falling water causes the millstone to turn which causes the grain to become flour and heat to be produced. Viewed from a different angle, two differences or tensions are produced in the course of the processes: grain versus flour and the temperature of the stones relative to that of the environment.

So far, the word ‘energy’ has not been used. We need this concept if we try to interpret the processes quantitatively through relations between amounts and differences. We can say that the falling water releases energy at a rate determined by the power of the process which depends upon the flow of water and the height of its fall. As the spin drops from the fast spinning runner stone to the stationary bedstone, it releases energy at the rate which is the power of the rotational process, and the energy released is used to produce flour and heat. Additionally, we see the energy released by the falling water as being transported to the waterfall, and the energy communicated from the water to the millwheel as being passed on to the millstones and finally to the flour and the heat that are produced.

The example of the description provided here can be transformed graphically using so-called process diagrams (Fuchs, 2010b, Chapter 2). To see this let us discuss a second example, that of heat driving an electric water pump (Fig. 4). If we have two bodies of water or any other material available—one hot, the other cold—we can operate a Peltier device in thermoelectric generator mode between the bot and the cold reservoirs. The Peltier device, in turn, drives the water pump.

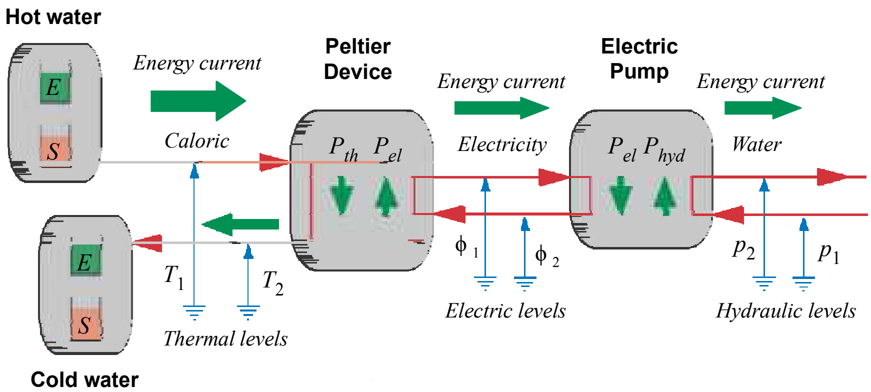

Figure 4. Process diagram representation of the chain of devices and processes leading from two bodies of water at different temperatures through a Peltier generator to an electric water pump. Fluidlike quantities representing the quantitative aspect of the FDG either fall or are pumped uphill and flow from device to device. Energy provides the coupling between processes in a device and the chaining of devices. Energy being released or used or flowing is represented by the green fat arrows. *P* denotes the power of a process.

The description goes as follows. Since the hot body of water gets colder in the process, and the colder one gets warmer, we interpret this as meaning that heat (caloric in Sadi Carnot’s sense) flows from the warmer to the colder body (see the left of the diagram in Fig. 4). It flows downhill from a warm place to a cold place. In other words, we interpret the temperature as the thermal level or potential. Heat falling from a higher to a lower level releases energy at a certain rate which is used by the Peltier device to pump electricity (electric charge) uphill (from lower to higher electric potential; see the central part in Fig. 4). The energy used to pump the electricity is passed on by electricity to the electric pump where it is released; note that the electricity flows downhill—from the higher to the lower electric level—in the pump. The energy released is then used by the pump to pump water which means that the pressure of the liquid is raised from a low to a high value (right side of Fig. 4). Finally, the energy used for pumping the water is transferred with the water.

We can use the idea of *differences* or *tensions* that has played such an important role in the previous examples as a fundamental descriptive tool. For example, as the gravitational tension of the water decays, a new rotational tension is set up which itself decays to set up new thermal and chemical tensions (heat and flour are produced). The world turns on this principle: tensions beget tensions that beget tensions…

What we have seen here can be transformed into a general approach to studying phenomena and formalizing our ideas of natural processes. The steps are the following: i) description of a process as a whole using common language; ii) refinement of the language used, stressing quantities that play a role; iii) description of the process in terms of fluid-like quantities, potential differences and associated elementary concepts (current, resistance, capacitance, etc.); iv) interpretation in terms of cause-and-effect (without using the word ‘energy’); v) introduction of energy quantities and energy balances. This method is appropriate for introducing pre-service and in-service teachers to narrative forms of descriptions of nature (supported by role games, stories, outdoors activities, laboratory work, drawings, writings etc.) that are eventually transformed into formal accounts. Most importantly, it is well suited to increasing levels of formalization and sophistication (from a qualitative approach using common language, up to quantitative procedures using graphs, maps, or mathematical relations). An entire graphical language, called process diagrams, has been developed that is intermediate between verbal descriptions and mathematical formulations (see Fig. 4; Corni at al., 2009; Fuchs, 2010b; Herrmann, 1998).

4. SUMMARY

If we follow modern cognitive science in general and cognitive linguistics in particular, we are led to identify basic figurative structures of the human mind which are used to conceptualize natural, psychological, and social phenomena and processes. We have introduced the Force Dynamic Gestalt as the cognitive structure that projects the schemas of quality/intensity, substance/quantity, and force/power onto phenomena, leading to metaphors. Processes are viewed as resulting from the flow of fluid-like quantities through differences of intensities (potential differences). They are forced by other phenomena, and they themselves force other phenomena in a chain of causes and effect. Energy is introduced as the measure of force/power of a process; in other words, it quantifies the relationship between cause and effect. Conceptualizing phenomena in this manner allows for a didactic approach that naturally leads from affective forms of narrative accounts to ever more formal descriptions. Linguistic and graphical tools have been developed that make this approach not only simple but also natural. It helps build the self-confidence of in-service and pre-service teachers since natural language serves as the steppingstone into the world of science.

SELF-DETERMINED LEARNING IN SCIENCE CLASSROOMS (GRADE 8) – AN EMPIRICAL STUDY

Anja Göhring[1]

[1]University of Regensburg, Germany

Abstract: The research project on Self-Determined Learning (SDL) represents an empirically tested educational approach based on the Self-Determination Theory (Deci & Ryan, 1993; Ryan & Deci, 2000a; Ryan & Deci, 2002b) and on specific teaching strategies. According to this theory instruction at school should emphasize the experience of competence (e.g. differentiation of tasks), of autonomy (e.g. free choice of activity) and the feeling of social relatedness (e.g. cooperative learning). With respect to these guidelines teaching units in physics (basic electricity and energy), biology and the German language which aim to improve instruction by enhancing Self-Determined Learning and achievement were developed.

The quasi-experimental study follows a treatment-control group design. To get information about the achievement in physics, the students were tested three times per teaching unit (pre, post and follow-up test). Questionnaires with psychological constructs for both students and teachers were used in addition as well as interviews and feedback sheets.

Analyses show (Göhring, 2010) that for example the experience of autonomy is significantly higher within the treatment group in contrast to the control group. Concerning other motivational constructs and achievement, there are in part opposite effects regarding the different types of school.

Keywords: Self-Determined Learning, science classrooms, physics education, empirical study, energy

BACKGROUND, FRAMEWORK AND PURPOSE

The research project SDL (Self-Determined Learning) represents an empirically tested educational approach based on specific teaching strategies. Teaching units in physics (basic electricity and energy), biology and the German language which aim to improve instruction by enhancing self-determined learning and achievement were developed. In the following I mainly restrict to aspects concerning the teaching unit on energy. The main contents are: definition of energy, different forms of energy and their transformation, energy in foodstuff, and saving energy at home (Göhring, 2010; Göhring & Laukenmann, 2006).

Instruction at school should take into account that both; cognitive and motivational aspects are important to initiating and fostering successful learning processes. The concept of this study is mainly based on the Self-Determination Theory according to Deci and Ryan (1993; Ryan & Deci, 2000a; Ryan & Deci, 2002b). Three basic human needs are of interest: the need to feel competent, the need to be autonomous and the need for social relatedness. Instruction at school should focus on these aspects, for example by differentiating tasks, by encouraging free choice of partners and of duration of activities, and by cooperative learning.

On the basis of this theoretical background, five educational guidelines were defined. For each educational guideline two teaching strategies were formulated: autonomy of the students (student centred instruction; activation of students), competence (differentiation of tasks; feedback), social relatedness (cooperation; play-like activities), structure (structured instruction; structured material) and relevance (authentic tasks; transfer). These guidelines and strategies describe the SDL-approach which is aimed at designing instruction that is more effective and more motivationally oriented.

RATIONALE

Education in Europe aims to foster personal autonomy and the use of both cognitive and affective skills to solve problems with regard to life-long learning (Hößle, 2004). As we know, motivation and positive learning emotions facilitate self-regulated learning (Boekarts, Pintrich & Zeidner, 2000). Within the Self-Determination Theory, Ryan and Deci make distinctions not only between intrinsic and extrinsic motivation but also between different types of extrinsic motivation (external, introjected, identified and integrated regulation). They emphasize the importance of a shift from mainly extrinsic to more intrinsic forms of motivation: *Frankly speaking, because many of the tasks that educators want their students to perform are not inherently interesting or enjoyable, knowing how to promote more active and volitional (versus passive and controlling) forms of extrinsic motivation becomes an essential strategy for successful teaching.* (Ryan & Deci, 2000a, p. 55).

METHODS AND SAMPLE

Each teaching unit was divided into two instructional phases (Weinert, 1999). Teaching in the first phase was carried out according to the following characteristics: highly student-centred instruction, no grades (but individual feedback), tolerance of mistakes, consideration of students' experience in everyday-life and their everyday concepts, self-regulated, activity-oriented and autonomous learning with many experiments, and cooperative learning. After the students received individual feedback based on special tasks, the second and shorter phase of the SDL concept focused more on the correction of mistakes and on students' learning success assessed through different types of additional exercises.

To test the SDL approach, a quasi-experimental field study was conducted during the school year 2005/2006 in 15 physics classrooms in south-western Germany (8^{th} grade, about 400 students and 15 teachers). The classrooms belonged to both low- and middle-level secondary schools. Eight teachers applied the SDL instructional approach in their classes (treatment group). Seven other teachers taught their classes (control group) in their usual way. All teachers taught the same content with the same learning goals over a period of about 17 lessons on basic electricity plus 14 lessons on energy.

As measures of achievement, one pre-test measure as a control variable (covariate) and two post-test measures as dependent variables were used. The pre-test measure was a test of students' pre-knowledge in the topics of electricity and energy. The first post-test measure of achievement was a graded class test which was relevant to the students' school reports. About six weeks later, a follow-up test measured the sustainability of SDL instructional units.

In accordance with the pre/post design, psychometric data were collected (from both; students and teachers) before the first instructional unit (time 1), between the two units (time 2) and after the second unit (time 3). In addition to questionnaires, feedback sheets were collected and interviews were conducted.

RESULTS

Motivational Constructs

To test the effects of SDL treatment on motivational constructs, multivariate analyses were computed using the General Linear Model (GLM) Procedure of the statistical software SPSS. In the GLM the fixed factors group, time and school types were included. The answering scale for every item reached from 1 (complete disagreement) to 4 (complete agreement).

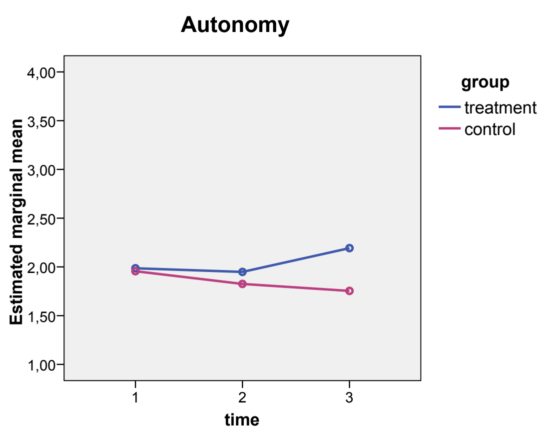

figure 1

Concerning the scale measuring Autonomy based on Röder and Kleines' (2003) autonomy scale (five items such as "In physics classes we can often choose between tasks on different levels"; $.65 \leq \alpha \leq .75$) a significant group effect was found (figure 1; $p < .001$, $eta^2 = .047$; $N = 330$). As intended with the concept, the treatment group felt more autonomous than the control group. Especially the second teaching unit on energy seemed to foster autonomy in classes quite well. Similar effects were found in low-level secondary school ($p = .011$; $eta^2 = .033$; $N = 136$) and in middle-level secondary school ($p < .001$; $eta^2 = .068$; $N = 194$).

Both scales measuring intrinsic motivation that is Interest Orientation and Competence Orientation (Lewalter, Schreyer, Wild, & Krapp, 1999) consisted of three items and showed good reliabilities ($.79 \leq \alpha \leq .87$; $.77 \leq \alpha \leq .87$).

Competence Orientation was ascertained with items like "Regarding physics I learn and take part in classes because it's important for me to improve my competence more and more". No significant group effect could be found for Competence Orientation but data showed an interaction time*group*school type ($p = .002$; $eta^2 = .019$; $N = 329$). While the treatment group showed a higher tendency of Competence Orientation than the control group in low-level secondary school ($N = 134$; n. s.), it was vice versa in middle-level secondary school ($p = .004$; $eta^2 = .029$; $N = 195$).

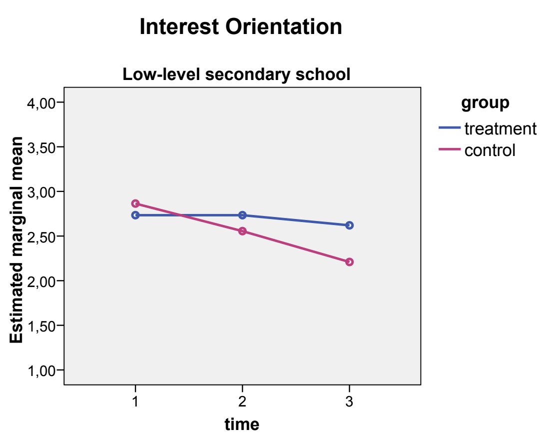

figure 2

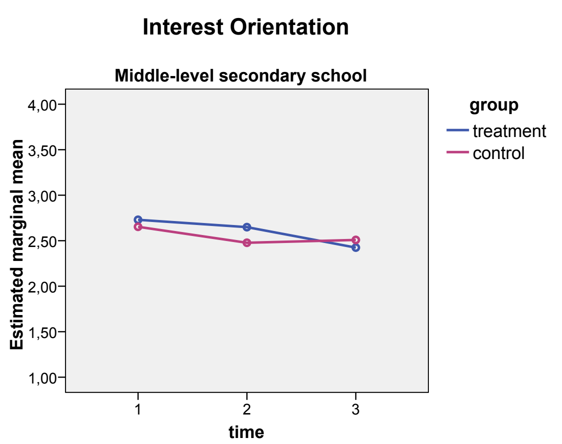

figure 3

“Regarding physics I learn and take part in classes because I’m very interested in the offered contents” was one of the items of Interest Orientation. Concerning this scale there was a significant group effect as expected ($p = .029$; $eta^2 = .011$; $N = 325$). Especially in low-level secondary school, SDL treatment was related to higher Interest Orientation (figure 2; $p < .001$; $eta^2 = .059$; $N = 133$). During the second teaching unit middle-level secondary school showed an opposite tendency again (figure 3; n. s.; $N = 192$).

Achievement

Regarding the development of achievement during the second teaching unit on energy, the General Linear Model (GLM) Procedure was computed again, this time multivariate with three covariates: class test and follow-up test of the first teaching unit and pre-test of the second teaching unit. All tests consisted of different kinds of tasks (reproduction, transfer, calculation) and the answering format was both prestructured and free.

In the graded class test on energy the students could obtain a maximum of 30 points. Concerning low-level secondary school ($N = 117$) the treatment group performed better than the control group (figure 4; middle-sized effect). In the follow-up test, with a maximum of 26 points to be obtained, the students of the treatment group did better on the test again, this time with a big effect-size (figure 5; $eta^2 = .259$). These results confirm the theoretical assumptions of Self-Determination Theory. As Self-Determined Learning is said to result in a better quality of learning it should foster achievement on the class test and especially the sustainability of learning on the follow-up test in this study.

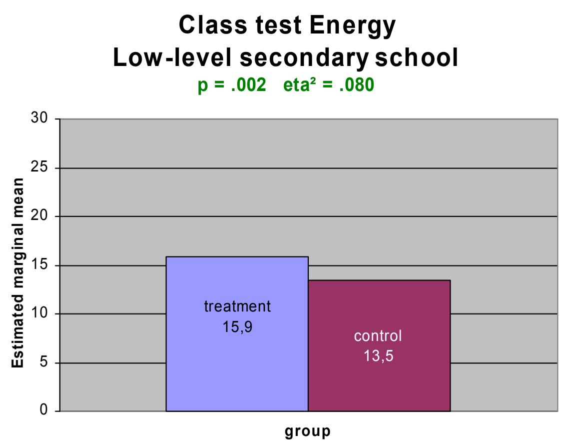

figure 4

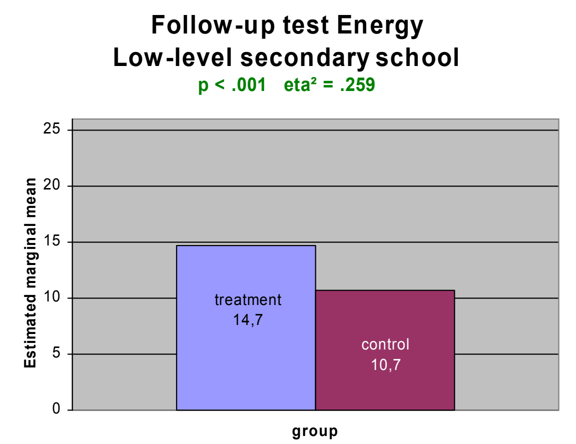

figure 5

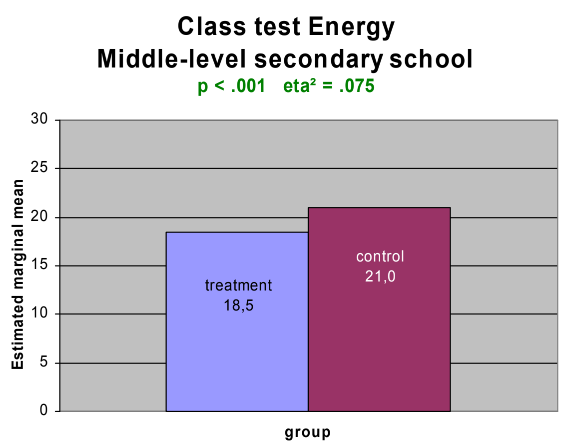

figure 6

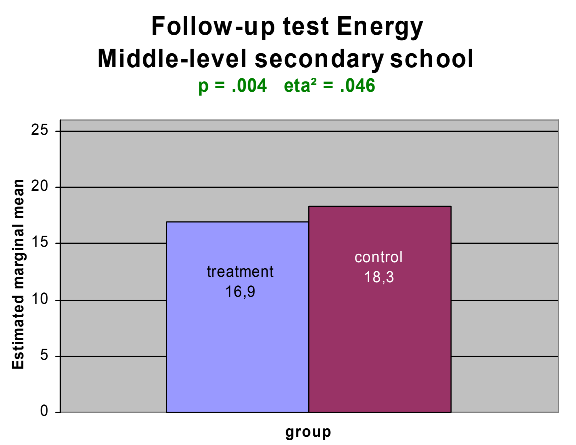

figure 7

Concerning middle-level secondary school (N = 182) unexpected results were found. There was also a middle-sized group effect in the class test, but the students of the control group performed better than the students of the treatment group (figure 6). A similar but low effect could be found in the follow-up test (figure 7).

Because of the unexpected results concerning achievement in middle level secondary school it made sense to pay attention to another scale of the students' questionnaire. With four items such as "Before a class test our teacher always says exactly what we should practice or repeat" the transparency of demands was rated by the students (using a modified scale originally developed by Ditton (2000); $.73 \leq \alpha \leq .77$). While there was no significant difference between the treatment and the control groups in low-level secondary school (figure 8; N = 137), the control group in middle-level secondary school showed a higher degree of Transparency than the treatment group (figure 9; $p = .001$; $eta^2 = .038$; N = 193). All teachers participating in the project were given the tests in advance but there were grounds for the assumption that especially the control group teachers in middle-level secondary school gave their students some extra training and more detailed information about the tests.

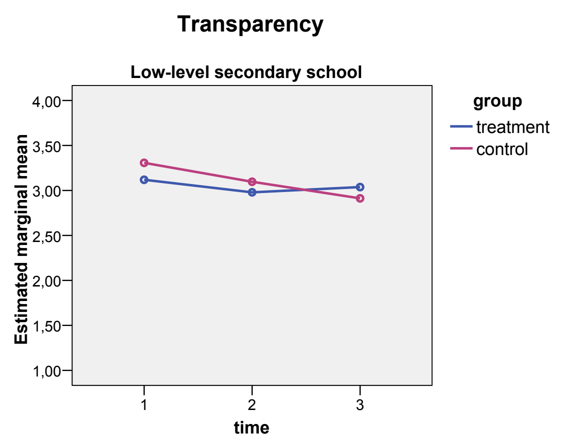

figure 8

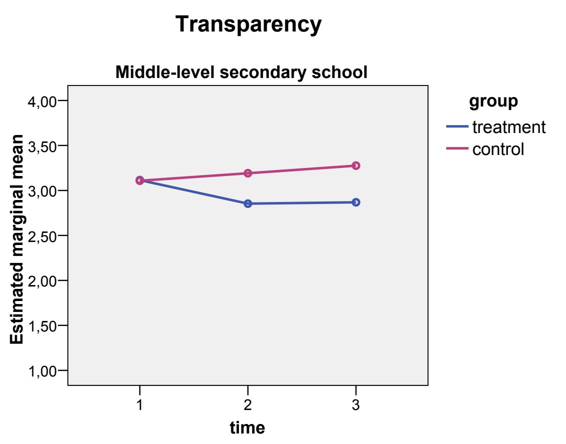

figure 9

Other indications might be the quality of intervention checked by the teachers' feedback sheets and investigations on class level. Some teachers of middle level secondary school didn't implement SDL concept as intended and one control class of middle-level secondary school was an outstanding high achiever class. For this reason it would have been better to have a sample of more than 7 or 8 classes of each school type or group.

Complex models

To evaluate the influence of different constructs on achievement regarding the second teaching unit on energy, analyses with Linear Structural Relationships (LISREL) were conducted. The overall model (figure 10) shows the relationship between different variables irrespective of the mode of group (treatment/control) or school type. Achievement on electricity was indicated by the class test and the follow-up test on electricity. Further independent variables were Transparency, Autonomy and Intrinsic Motivation (Competence Orientation, Interest Orientation), all measured to time 3 at the end of the teaching unit on energy. As to be seen on the left hand side of figure 10, the correlations between these variables are low and only in part significant; the assumption of independent constructs is thus justified. On the right hand side, the strong relationship (direct and indirect) between the achievement on electricity and the different measures of achievement on energy stands out.

Regarding the motivational constructs, a significant path to the sustainability of SDL instructional unit energy was only found from Intrinsic Motivation (0.14**). If the complex model is calculated separately for the treatment group, this path is 0.25** and the linear effect concerning the treatment group of low-level secondary school is even 0.45*** that is 20 % of the variance. Overall, one conclusion might be that achievement in physics is very stable and can hardly be influenced.

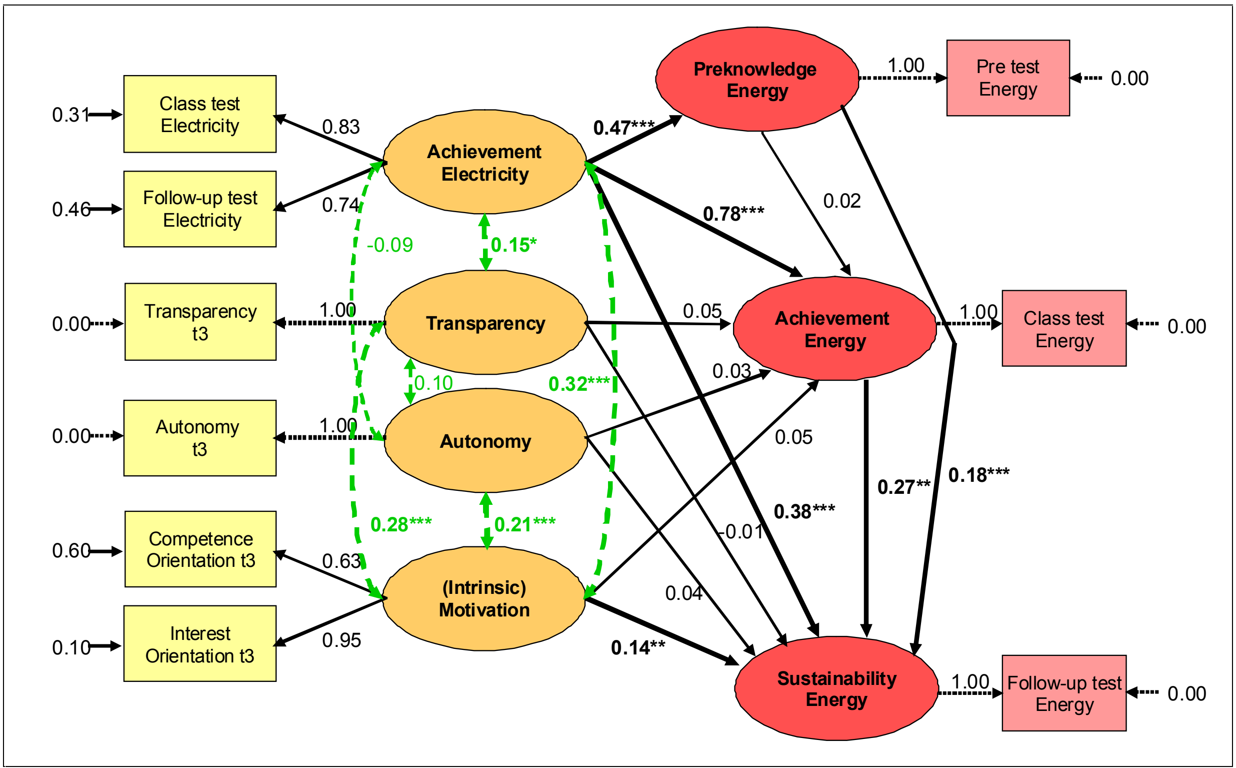

figure 10: LISREL model (total); Chi² = 14.84; df = 14; p = 0.389; RMSEA = 0.014; N = 288

CONCLUSIONS AND IMPLICATIONS

Analysis of the data shows interesting effects of SDL on motivational constructs and achievement (Göhring, 2010). Regarding low-level secondary school, SDL concept often has an effect as was expected, in contrast to middle-level secondary school treatment. Based on further analyses of the teachers' feedback sheets, the quality of intervention was not as intended in some classes of middle-level secondary school (e. g. less time, in part no experiments and cooperative learning). Furthermore, complex models (Linear Structural Relationships) show on one hand a significant path from Intrinsic Motivation to the sustainability of SDL instructional unit energy, but on the other hand the stability of achievement in physics. Greater variance concerning sustainability (energy) is explained by the achievement in electricity. Another reason for why motivational effects of the SDL treatment are lower than expected may be that motivation in the learning process is more closely related to personal aspects (e. g., teacher-student relationship; Gläser-Zikuda, Fuß, Laukenmann, Metz, & Randler, 2005) than to instructional methods. Thus an educational intervention focusing not only on instructional methods but also on the way of communication and interaction between teacher and students may be more successful in influencing students' motivation.

THE INFLUENCE OF INTERCONNECTEDNESS AND PROBLEM-ORIENTATION ON ACHIEVEMENT IN CONTEXT-BASED LEARNING

Andrea Harbach[1] and Sabine Fechner[2]

[1]Department of Chemistry Education, University of Duisburg-Essen, Germany

[2] Department of Chemistry Education, Leibniz University Hannover, Germany

Abstract: Context-based learning is a widespread learning approach in German science teaching. Important features of this approach are the interconnectedness of context and chemical content as well as a focus on problem-orientation. Although it could already be shown that context-based learning has a positive influence on the interest of students, the results concerning their achievement are inconsistent. This could also be due to the lack of knowledge how to design a context to make chemical content clearer instead of more confusing. Hence, this project will investigate the influence of the above mentioned features, e.g. degree of interconnectedness and problem-orientation, on student achievement. Thus, self- learning texts were developed that vary according to these characteristics. Afterwards an intervention took place in which ninth-grade students worked on the self-learning texts. The study follows a pre-post-test design. The results of the pilot study show no significant difference in achievement for the different self-learning texts. However, results tend to show differences concerning the variable *problem-orientation* and its interaction with the variable *context* and *interconnectedness*. Therefore, the main study is conducted with a larger sample size and four self-learning texts for each student in autumn/winter 2011/2012 to confirm the results of the pilot study.

Keywords: context-based learning, problem-orientation, text learning

INTRODUCTION

Objectives

Context-based learning is a widespread and popular learning approach in chemistry education. Important characteristics of context-based learning are problem-orientation (Demuth, Gräsel, Parchmann, & Ralle, 2008) and the interconnectedness of everyday life contexts (e.g. food) with chemistry-related content (e.g. substances and their properties, conservation and changes) (Parchmann & Demuth, 2004; Parchmann et al., 2006). Studies show that context-based learning influences student interest and attitudes in a positive way (Bennett, Lubben, & Hogarth, 2007). Moreover, students in context-based learning environments also outperform their counterparts in traditional instruction under certain conditions (Fechner, 2009).

Based on this, the question arises why it is still necessary to investigate context-based learning. First, there are few studies and most of them struggle with methodological problems. For instance, they do not have a pre-post-test design, fail to eliminate confounding variables or do not randomize (Taasoobshirazi & Carr, 2008). Second, a high motivation or interest in the used contexts may not necessarily lead to higher achievement. Contexts, for example, can confuse the learner by activating irrelevant schemata which are closely related to the respective context but not to the chemistry-related content (Park & Lee, 2004). Third, it is not clarified which further context characteristics promote learning and how contexts have to be designed to make chemistry-related content clearer instead of more confusing (Park & Lee, 2004; Schwartz, 2006). Hence, the question is whether interconnectedness of context and content as well as problem-orientation, which are important characteristics of context-based learning as mentioned above, are also factors of influence on student achievement. For this reason, the following research questions will be investigated in this study on the basis of an experimental design:

RQ 1: Which influence does the degree of interconnectedness between chemistry-related content and everyday life context have on student achievement?

RQ 2: Which influence does problem-orientation have on student achievement?

RQ 3: If an interaction between problem-orientation and interconnectedness exists, of what kind is it?

RQ 4: Which influence on achievement is higher if the effects of problem-orientation and everyday life context are compared?

Theoretical Background

Apart from problem-orientation and interconnectedness, some other factors of influence on achievement can already be identified: Gomez, Pozo, and Sanz (1995) reveal that using different contexts causes different learning progress if the underlying content is the same. In addition, Song and Black (1991) demonstrate how the kind of learning task has an influence on learning progress. In their study, they use two different learning tasks (interpretation and application) and contexts (science and everyday life context). The combination interpretation task and everyday life context as well as application task and science context lead to the highest learning progress. A third factor of influence seems to be the personalization of learning tasks. A study by Son and Goldstone (2009) suggests that personalization affects learning, especially transfer.

METHODS

Study Design

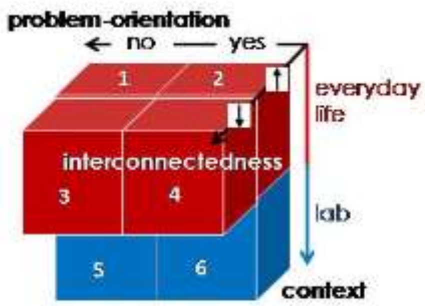

Figure1. The variation of the variables

Regarding the research questions, the study investigates three variables and their influence on achievement: context, problem-orientation and interconnectedness between context and chemistry-related content. To vary these characteristics, self-learning texts were developed in which these variables were realized. Each variable has two parameter values: high vs. low interconnectedness (RQ 1 & 3), problem-orientation vs. no problem-orientation (RQ 2 & 3) and everyday life context vs. laboratory context (RQ 4). In Figure 1, the three variables and their parameter values are presented. Each box represents one kind of self-learning text. Cell No. 1 for example, represents a non-problem-oriented, highly interconnected self-learning text, which is embedded in an everyday life context. Because of the fourth research question it was sufficient to develop self-learning texts that are embedded in a laboratory context and show only a high interconnectedness, as you can see in Figure 1 (RQ 4). Altogether, six different self-learning texts were designed based on the same chemistry-related content. To generalize results across different content areas, this variation of variables was accomplished for four different chemistry-related contents (e.g. *salts*) (see

Table 1). In summary, 24 (different contents*number of treatments; 4*6) self-learning texts were designed.

Table 1. The four chemistry-related content areas

	chemical content areas
1	salts I
2	salts II
3	acid & bases I
4	acid & bases II

The study employs a pre-post-test design. First, a pre-test is conducted, in which a content knowledge test is administered to students. Control variables like verbal ability and interest are also retrieved**.** Thereafter, the intervention proceeds and students work on the developed self-learning texts. Finally, a post-test follows using a content knowledge test and situational interest questionnaire (for an overview see Table 2).

Table 2. Test instruments

	control variables
pre	*interest questionnaire* (Fechner, 2009)
	verbal ability (one chart) (Heller & Perleth, 2000)
	dependent variables
pre & post	*content knowledge test* consisting of reproduction and application items; topics: acids & bases and salts (according to Koelbach, unpublished)
post	*situational interest* (Fechner, 2009)

Pilot study

To evaluate our test instruments, a pilot study was conducted in winter 2010/2011. In this study content area number 3 (see Table 1) was tested because no evaluated achievement test was available here. An overall number of 190 students (approximately 30 students per cell) participated. Students attended the 9th grade of an upper secondary school (Gymnasium). Two lessons á 45 minutes were necessary to conduct the study. During the first appointment, a test on prior knowledge (content knowledge test) and verbal ability was administered. The second time, interest data was collected and the intervention proceeded. Afterwards, the students had to fill in the content knowledge test and a situational interest questionnaire.

VARIATION OF VARIABLES

To vary the self-learning texts systematically concerning the three different variables, all self-learning texts consist of chemistry-related and contextual statements. The chemistry-related statements are sub-divided into concrete and general statements. Table 3 provides examples for the different types of statements.

*Table 2***.** Types of statements in a developed text

chemistry-related statements		contextual statement
general statement	**concrete statement**	
Salt dissolves in water because it is polar.	Potassium nitrate dissolves in the ground water because it is polar.	Fertilizer could dissolve in the ground water and transported by rain to a close swimming lake, because it is a salt mixture.

Variable *interconnectedness*

Self-learning texts are developed with either a high or a low degree of interconnectedness. High interconnectedness implies a high connection between context (e.g. *pollution of a lake)* and the chemistry-related content area whereas lowly interconnected self-learning texts show a low connection between those two aspects. For both types of self-learning texts, the general statements are the same, whereas the concrete and contextual statements are varied (see Table 4). If there is a low degree of interconnectedness, neither contextual words are embedded in chemistry-related statements (see last row/middle column) nor are chemistry-related words embedded in contextual statements.

Table 3. The variation of the variable *interconnectedness*

	chemistry-related statements		contextual statements
	general statements	**concrete statements**	
high interconnectedness	Salt dissolves in water because it is polar.	*Fertilizer* dissolves in the *ground water* because it is polar.	The fertilizer could dissolve in the ground water and transported by rain to a close swimming lake, *because it is a salt mixture.*
low interconnectedness		*The mixture* dissolves in *water* because it is polar.	The fertilizer could dissolve in the ground water and transported by rain to a close swimming lake.

Variable *problem-orientation*

In addition, self-learning texts were developed with and without problem-orientation. Problem-oriented self-learning texts start with a problem and explain it with the help of the content.

Table 4. The variation of the variable problem-orientation

	problem-orientation	no problem-orientation
order of statements	contextual statements	-
	problem	presentation of the content
	concrete statements	general statements
	general statements	concrete statements
	-	contextual statements

Without problem-orientation the self-learning texts start with the content and use the context as an application at the end of the text. Both self-learning texts consist of contextual and general as well as concrete chemistry-related statements (for an example see Table 5). The difference can be found in the sequence of statements: Problem-oriented self-learning texts present concrete statements before the general statements follow. In non-problem-oriented texts it is vice versa.

The variable *context*

Moreover, the variable *context* has two parameter values: everyday life and laboratory context. The resulting texts differ concerning their contextual and concrete statements. To make the texts comparable, almost the same amount of words and a similar sentence structure was used for the contextual statements. Concrete statements differ only in words. For instance, in self-learning texts, which are embedded in an everyday life context, the word *fertilizer* is used. In comparison, self-learning texts, which are embedded in a laboratory context, the word *chemical* is used instead of *fertilizer*. Each of the content areas is embedded in two contexts, meaning everyday life and laboratory. Table 6 presents the used contents areas and their contexts.

Table 5. The content areas and contexts

chemical content areas	contexts	
	everyday life	laboratory
salts I	pollution of a lake	analysis of idodide
salts II	polluted drink water	colour of a salt solution
acid & bases I	heartburn	disposal of a solution
acid & bases II	teeth & juice	identification of a solution

RESULTS

The results presented in this section refer to the conducted pilot study (content area 3).

As shown in Table 7, the total scale of the achievement post-test shows good internal consistency. Considering the subscales, differences in the internal consistency can be noticed. This probably depends on the amount of items. Thus, for the main study more application items have been constructed to raise internal consistency.

Table 7. Test parameters of different content knowledge measures (description, internal consistency estimate and number of items)

content knowledge post-test	description	α	Items
total scale		.931	36
recall	recalling uncontextualized facts or concepts	.900	24
application-inside the subject	narrow transfer of facts and concepts	.763	5
application-everyday life	applying concepts to unknown problems in the *real world*	.511	3
application-laboratory	applying concepts to unknown problems in the *laboratory*	.611	4

Concerning the learning gains induced by the texts, a paired *t*-test was conducted to determine whether the increase in learning caused by the texts was significant. It reveals that achievement increased significantly for all students ($t(185) = 11,863$; $p < .001$).

An ANOVA was used to test the influence of context (laboratory or everyday life), problem-orientation (yes/ no) and interconnectedness (high/low) on achievement. With reference to the whole sample, the results show no significant difference in achievement for the different self-learning texts (p = n.s.). Considering sub-groups, female students have the highest achievement in application items for highly connected, problem-oriented self-learning texts ($F(1,54) = .110$; $p < 0.05$, *part.* $eta^2 = .086$) (RQ 3). There are also some interesting tendencies: Self-learning texts with problem-orientation tend to lead to higher achievement levels in application items (RQ 2). Additionally, problem-oriented self-learning texts may lead to a higher learning outcome if they show a high degree of interconnectedness (RQ 3). Furthermore, in problem-oriented self-learning texts - if embedded in an everyday life context instead of laboratory context - students tend to learn more.

CONCLUSION & IMPLICATIONS

As mentioned above, the overall sample does not show significant differences in achievement concerning the different variables. This may be caused by several reasons: First, the small sample size might be responsible and tendencies might be confirmed in the main study. Tendencies comprise differences concerning the variable *problem-orientation* and its interaction with the variable *context* and *interconnectedness* (see results). Second, the type of self-learning text may have an influence by not allowing a high variance. Third, it can be assumed that students are used to learn from texts in a traditional way (non-problem-oriented) because most textbooks are structured like this. Achievement results might be better if they get used to the problem-oriented text by repeatedly being exposed to it. In consequence, each student will work on four self-learning texts in the main-study.

AUTHENTIC INQUIRY LEARNING: STUDENTS AND SCIENTISTS "ON EQUAL TERMS"

Christine Heidinger[1] and Franz Radits[1]
[1]Austrian Educational Competence Centre Biology, University of Vienna, Austria

Abstract: In many developed countries, science systems seek solutions to encounter the problems of traditional science curricula (e.g. lack of engagement by students, poor image of science). Inquiry learning at authentic study sites is a promising approach to address this issue. In the research and development project "Kids Participation in Research" (KiP), five scientists from the Faculty of Life Sciences, University of Vienna, invited ten science classes (~200 students, aged 11-17 years) to their research facilities to work collaboratively on their current research topics. By providing authentic learning environments for inquiry learning, KiP aims to enhance the students' scientific literacy. The working model in KiP relies on three main features: authenticity, inquiry learning and cooperation "on equal terms". The students work together with real scientists, in their authentic laboratories, on their current research questions. Moreover, they negotiate their understanding of scientific issues with the scientists' views, on equal terms. This focus on students' perspectives in the course of science learning is derived from the learning theory underlying the model of Educational Reconstruction. Scientific concepts and the concepts held by students are both viewed as constructs which are negotiated on equal terms in order to reconstruct scientific contents based on the students' perspectives. This is a prerequisite for effective science learning, and KiP strives to apply this rationale to a dynamic, authentic learning environment. This paper presents the working model of the KiP project and discusses the results of its evaluation based on data from the project's pilot phase.

Keywords: authentic science, scientific inquiry, student-scientist partnerships, scientific literacy, educational reconstruction

INTRODUCTION

The research and development project "Kids Participation in Research" (KiP) creates an authentic stage for students to encounter scientific research at the University of Vienna. Scientists from various fields (e.g. neurobiology, palynology, marine biology) invite school classes to their research facilities. KiP is being funded by the Austrian Federal Ministry of Science and Research as part of the program "Sparkling Science" (www.sparklingscience.at). This program is designed to sustainably improve the interface between the school system and universities in Austria. This attempt is not unique. In many developed countries, science systems seek solutions to encounter problems of traditional science curricula such as lack of engagement by students, poor image of science, and insufficient teacher competence. The goal is to promote the development of a citizenry of scientifically literate persons and inspire young students to choose a science-related career (Stockelmayer, Rennie, & Gilbert, 2010). Promising attempts to meet these ambitious aims include cooperation between schools and universities, with student-scientist-partnerships being one concrete form of such cooperation (e.g. Sadler, Burgin, McKinney, & Ponjuan, 2010; Roth, van Eijck, Hsu, Marshall, & Mazumder, 2009; Tytler, Symington, & Smith, 2011). Such science apprenticeship programs often see themselves as an alternative educational approach for science learning compared to an out-dated and less valid school science which fails to convey the nature of scientific concepts and research methods (Braund & Reiss, 2006; Stockelmayer, Rennie, & Gilbert,

2010). Instead, giving students authentic insights into science in the course of a research apprenticeship program is assumed to portray a much more realistic image of science. The meta-analysis of such learning environments carried out by Sadler and colleagues (2010) revealed many positive outcomes: Amongst others, knowledge about the Nature of Science (NoS) could be enhanced and students developed a greater confidence for doing science. But the authors also conclude that there is a lack of "finer grained analysis of specific programmatic features" (Sadler, Burgin, McKinney, & Ponjuan, 2010, p. 253) of these learning environments.
We would like to meet this demand in our work. In KiP we have developed a theory-based working model for student-scientist-partnerships. It is designed to improve the learning processes of students (and their teachers) in terms of their knowledge about the NoS and their scientific literacy. In a next step, we would like to gain a deeper understanding of the processes we launched by focusing on the effects of the specific features of the learning environment in KiP.

RATIONALE

The KiP working model relies on three main features: authenticity, inquiry learning and participative collaboration. Authenticity refers to the collaborative work with real scientists, in their authentic laboratories, on current research questions. The positive effects of this practice on students' understanding of scientific knowledge and methods have been reported by various authors (e.g. Sadler, Burgin, McKinney, & Ponjuan, 2010; Roth, van Eijck, Hsu, Marshall, & Mazumder, 2009; Tytler, Symington, & Smith, 2011). Within this mutual work, students get the chance to conduct their own research projects while being mentored by the scientists. Teachers and educational researchers are also part of this cooperation and have mainly supportive roles.
KiP goes beyond authenticity and inquiry learning to follow a participatory rationale. All KiP stakeholders are challenged to act on equal terms. We try to reach this ambitious aim by installing a respectful atmosphere in the project so that the beliefs and opinions of all stakeholders are taken seriously.
In this paper we focus especially on the evaluation of the third feature of KiP: the participatory rational. According to the learning theory for science contents underlying the model of Educational Reconstruction (Kattmann, Duit, Gropengießer, & Komorek, 1997; Kattmann, 2005, 2007), this egalitarian approach is expected to positively affect science learning by the students. The model of Educational Reconstruction was primarily introduced to develop science teaching curricula in school settings. Following a constructivist understanding of learning processes and knowledge production, scientific concepts and students' conceptions are both treated as constructs. They are negotiated on equal terms in order to develop curricula which improve science learning. The development of the curricula demands a reconstruction of scientific concepts based on students' perspectives. On the one hand, this process involves students' perspectives about a given science content. On the other hand, it includes broad information resources about the science content including research papers, textbook knowledge, references to the philosophy and history of science. This process reveals a science content which is much more enriched compared to abstract canonical concepts. It is assumed to bare the essences of a scientific content in a way that students are able to generate a deeper understanding of it.
The novelty in KiP is that it applies the rationale behind the model of Educational Reconstruction to dynamic, authentic learning environments. Reconstruction of scientific content is not the task of an educational researcher in advance of science lessons. Rather, this process should evolve "live" through the mutual work of and discourse between scientists,

students, teachers and accompanying educational researchers, all of whom are committed to collaboration on equal terms.
The evaluation of the working model in KiP is based on data from the 2008-2010 pilot phase in which five scientists from the Faculty of Life Sciences, University of Vienna, worked together with ten science classes – about 200 students aged 11-17 years and ten teachers.

RESEARCH QUESTIONS

The main research question of this paper is: Does the working model in KiP succeed in implementing authentic environments for inquiry learning that are beneficial for science learning?
The overriding research question is answered by referring to the following, more narrow questions: Are scientific concepts reconstructed by incorporating students' concepts? Are scientific concepts and students' concepts negotiated on equal terms in KiP?

CONTEXT AND DATA

One out of nine sub-projects in KiP was analysed. In this sub-project, known as NEURO-KiP, students from a secondary school in Vienna (10^{th} grade) together with the Department of Neurobiology and Cognitive Research at the University of Vienna (an assistant professor and his PhD student) investigated the spider *Cupiennius salei*, a model organism. Two teachers and educational researchers were also part of this cooperation.
The data for the present contribution were collected mainly by recording the dialogues between the stakeholders in NEURO-KiP at the meetings.

METHODS

The transcriptions of dialogues were analysed by qualitative content analyses based on research strategies derived from the model of Educational Reconstruction (Kattmann 2007). In a first step, the contents negotiated between the stakeholders in NEURO-KiP were categorized. Then, potential cognitive concepts underlying the students' and the scientists' statements were revealed by adopting a hermeneutic approach.
The results show that some sequences in the conversation were especially fruitful for the analysis: These were passages in which the students provided an incorrect answer to a scientist's question because of a lack of understanding or because the students didn't believe in the knowledge claims of the scientist and argued against it. These passages revealed different underlying concepts, and they provided enough material to substantiate these concepts. Finally, post-interviews with all stakeholders were used for communicative validation of the results.

PROCESS ANALYSIS

Before presenting the results of the process analysis it is useful to examine the NEURO-KiP framework: The professor suggested working on a specific experimental design that is currently being investigated at his department. The experiment focuses on the visual orientation of the spider *Cupiennius salei* – a spider inhabiting the rain forest in Central America. The scientists are interested in determining the criteria a spider uses in choosing a tree to climb on and ask the research question "What makes a tree 'attractive' for a spider?". This is examined in a behavioural choice experiment where two stimuli (black bars) – which represent trees and which differ in only one parameter – are presented to the spider. The stimulus to which the spider runs is then observed (see Figure 1). From the results of this experiment, inferences can be drawn on the functioning of the spider's visual orientation system.

Figure 1: Authentic, experimental design in the scientists' research field

It was the students' task in NEURO-KiP to work on this authentic experimental design. They developed and carried out their own experiments within this design to answer the research question. Throughout the project the practical work was accompanied by intensive discussions between the students and the scientists. The discourse was dominated by the students' problems in understanding and accepting the highly reduced experimental design of the scientists. This is evident in the following student statements during the process:

Student:	The problem that I see is whether the spider thinks that these black bars are trees. How can the scientists know that?
Student:	Did you try with a real tree?
Student:	We always assume that the spider perceives the stimuli as a tree where it can live. But maybe it only perceives them as a form, to which it runs because it seems to be interesting for the spider.
Student:	And how do you know now that the spiders which grow up in nature where totally different factors are present, a lot more trees and other things, that these spiders follow the same laws like the spiders in this box?

These statements demonstrate what the process analysis revealed: Students intensively questioned the external validity of the experiments in multiple ways. From their perspective, knowledge about the behaviour of the spider in the laboratory can't be transferred to the behaviour of the spider living in its natural habitat. The students apparently had major problems in understanding and accepting the scientific method of parameter reduction. Instead of installing a laboratory experiment with a highly reduced environmental stimulus rate, they first even suggested constructing a biotope in order to design an experimental environment closely resembling the natural habitat of the spider (rain forests). The students assumed that one can only gain knowledge about the behaviour of the spider if it is examined in its natural habitat. The scientists, in contrast, argued that it is only possible to gather definitive knowledge if the behaviour of the spider can be traced back to only one parameter. During the course of the cooperation process, it turned out that two very different models of the spider as an organism underlie the opposing concepts. These are mirrored in the suggested experimental designs to answer the research question the scientist posed: While the students think of the spider as an individual which can control its behaviour and probably has a free will to act, the scientists think of the spider as a machine-like organism which automatically reacts to sensory input.

In addressing the doubts of the students and their problems in understanding the scientific view, the scientists referred step by step to the extensive knowledge on which the current experimental work is based. This led to highly enriched science contents and uncovered nature of science aspects. An example: At the beginning the scientists only declared that it is important to reduce parameters in a scientific experiment in order to be able to interpret the data. During the process the scientists were called upon to illuminate the process by which parameters are chosen and reduced: The scientists therefore referred to their model of the spider and to the huge number of earlier experiments that justify reducing a tree to a bar.

RESULTS

With regard to the research questions raised by the present paper, the conclusion is that scientific constructs are reconstructed by the scientists depending on the students' concepts in NEURO-KiP. The scientists needed to introduce numerous references which were important for students to understand and accept the experimental design. These steps were triggered by student questions, by incorrect answers to questions posed by the scientists, by the students' articulation of doubts and, of course, by the scientists' ability to provide all this background information. Does that, however, also mean that students' and scientists' concepts were negotiated on equal terms? Only partly. On the one hand, students were free to articulate their thoughts even if it meant that they questioned a scientist's work. On the other hand, the concepts of both stakeholders were not treated equally. Students' considerations about the reasons for the spider's behavior were, for example, often classified as "false" and not as different conceptions.

CONCLUSIONS AND IMPLICATIONS

This work revealed that the model of Educational Reconstruction is very valuable for developing effective authentic environments for inquiry learning. It is also an appropriate approach for gathering knowledge about the cooperation processes taking place in these environments during educational research. Regarding the evaluation of the working model in KiP, the results show that many important criteria of the learning theory underlying the model of Educational Reconstruction were successfully installed "live" in the cooperation process in NEURO-KiP. At the same time, the KiP working model may lack a reflective element that yields information about students' and scientists' concepts *during* the cooperation process and that renders it visible during the cooperation. This would have helped to negotiate students' conceptions and scientific constructs on equal terms. The assumption, according to the model of Educational Reconstruction, is that in this case students would have gained an even deeper understanding of the nature of science.

LADS IN PHYSICS CLASSES: INTERACTIONS BETWEEN MASCULINITIES AND LEARNING OPPORTUNITIES

Josimeire M. Julio[1] *and Arnaldo M. Vaz*[2]
[1]Universidade Federal de São Carlos/Brazil
[2]Universidade Federal de Minas Gerais/Brazil

Abstract: We investigated the influence of certain configurations of masculinity in the development of Learning Opportunities in upper secondary school physics classes and – reciprocally – the influence of Learning Opportunities experienced by students in the process of producing resistance patterns, power relations and collaboration in a group of three lads in a room class. Research design was based on the dovetailing of a Social Theory of Gender's analytical framework with classroom observation of ethnographical perspective. Along one year, we Observed one entrants 'Grade 10 class from within the classroom along one year and only then conducted in depth analysis of audio and video recording of anyone specific activity, Tone that Simulates Scientific team's work;. This activity occupied it ran for six lessons for that class, early in the school that year. Such The microanalysis of one group during this activity enabled us to characterize common interactions among lads its components. The results indicate that the interactions occurred in the learning groups according to profiles of masculinity that figure among students and interfered with Learning Opportunities that they experienced. The interactions between the guys in the group analyzed, shaped the standards of strength, power relations and collaboration that have been modified by the intervention of the teacher.

Keywords: learning opportunities; investigation activities; interaction between masculinities; learning groups physics learning

BACKGROUND, FRAMEWORK, AND PURPOSE

We have developed a theoretical-methodological construct to identify and analyse aspects that are not explicit or not conscious in the social interactions in Physics classes. Here, in particular, we focus on aspects of these interactions that determine gender configurations, standards of resistance and internal disputes. This investigation shows that they occur in learning groups and bring implications for students' individual and collective learning. We gave priority to aspects of these interactions that are related to the processes of construction and internalization of masculinities and that exert influence, both in the classroom dynamics, as well as in the constitution of the social identities that are built up within teaching/learning context of school Physics. We have established the connection between these elements appealing to Connell's social theory of gender (1995) and to the interactional ethnography concept of *Learning Opportunities*.

According to interactional ethnography, *Learning Opportunities* are the situations in which the students construct and embody meanings by means of verbal and nonverbal communication in social speech constructed in the coexistence in the classroom (BLOOME & BAILEY, 1992; REX; STEADMAN & GRACIANO, 2006). From the point of view of the interactional ethnography, the knowledge, the practices and the actions are located outside of the thought of the individuals, each one of them appears in the interaction that occurs between these individuals (JORDAN & HENDERSON, 1995). The mapping of these interactions makes possible the identification of the configurations of the masculinities and of the *Learning Opportunities* that are configured in this environment.

Connell (1995) refers to masculinity as a position on gender relations which has an influence on a person’s practices and ways he relates to physical, personal and cultural experiences. Therefore, different masculinities might be manifested, even on one single individual.

Haenfler (2004) argues that hegemonic masculinity of western values and legitimizes particular competition, hierarchy, individualism, sexual prowess, body strength, rationality, emotional distance, domination and courage to take risks. Connell (1995) identifies the interaction between groups of men alternating between patterns of resistance, power relations and collaboration that are configured around four standards of masculinity: hegemony, subordination, complicity and marginalization.

The hegemony refers to the cultural dynamic in which one group wins and maintains its leadership position in social life, she secures the position of male domination and subordination of women. This is the essence of hegemonic masculinity.

The subordination refers to the inferior position of women and men's groups that are outside the circle of legitimation of hegemonic masculinity. Homosexuals are the most representative case, but groups that have symbolic similarities with the women also fall in these groups being taxed by an abusive vocabulary - "nerd" mama's boy, coward, "woman," among others. The marginalization refers to the way in which some individuals subordinate groups by race and social class factors external to the gender order, stand as representatives of hegemonic masculinity of the dominant group. The protest masculinity is characterized when the focus turns into anti-school attitudes, aggression, transgression, and, ultimately, into social violence.

The complicity to men in general guarantees the privileges acquired by the patriarchy. It allows the connection to the current hegemonic project, even if the rules are not adopted strictly hegemonic. In this group fall the men of reason.

In western culture, scientific knowledge is many times associated with male characteristics. Physics, for instance, is iconic of an ideal rationalism, much valued in the west. The relations between different individuals that are established within classroom are determined by the interactions between different masculinities, the individuals' relation with Physics and with school, other individual characteristics and their learning potential. In this coexistence, they negotiate actions, construct and internalize social meanings and identities. We understand that, in this encounter, the specific masculinities valued at a certain moment define *Learning Opportunities* in Physics. We consider that there is a reciprocal interference between masculinities configurations and *Learning Opportunities*. We investigate how the masculinity standards intervene on the elaboration of *Learning Opportunities* and how the *Learning Opportunities* that the pupils lived interfere in the producing process of resistance standards, power relations and collaboration in masculine groups in a classroom.

In this paper, we analyse the interactions lived deeply in a group of lads, looking for masculinities standards that they reveal individually, the relations that they establish between them by means of these masculinities and the *Learning Opportunities* built in this process.

METHODS

The university committee on ethics in research involving human beings approved the procedures we planned to observe during the conduction of this investigation. We made audio and video recordings of male and female students, but only those that agreed to voluntarily take part; their parents also manifested approval of research use and diffusion of these data.

Along one year we stayed within the classroom and observed 17 boys and 8 girls of one Grade 10 class in an upper secondary federal school (Grade 10 to 12). Based on these observations of ethnographic character, we conducted ethnographic microanalysis of audio and video recordings of one teaching sequence which occupied six lessons, early that year. In this teaching sequence, the class was arranged in 9 groups of three or four students each. The challenge for them was to investigate a natural phenomenon. We analysed data as in descriptive research: familiarity with individuals and class gained on the year-long observations helped us to analyse dominant characteristics of the way individuals and groups worked during these six lessons. Descriptions allowed new analyses of episodes that focused on: (a) the relation between pupils within a group; (b) the relation between the group and the activity; (c) the relation the group established with Physics; (d) the relation between the group and other context elements, such as teacher and other groups.

Data gathered conducted to (i) identification of common characteristics of boys involved in the learning situation; (ii) descriptive characterization of aspects that facilitate boys' action; (iii) descriptive characterization of aspects that inhibit boys' action; (iv) comparison between results obtained in steps 'ii' and 'iii' for different kinds of learning situations according to two points of view, that of configurations of masculinities and that of the *Learning Opportunities*. In this paper we produce analysis of a single group due to the characteristics of its components and the generalisability of its analysis. Each of the three lads in the group acted according to one of the different masculinity pattern conceived by Connell (1995). Consequently, by analysing their actions along the activity we could see differences on how they created *Learning Opportunities* along the way.

The group that stands out here are due to the different profiles of masculinity that make up the group dynamics and the learning opportunities of its members. The characterization presented below for each of the boys who make up the group you want to get to know the aspects of masculinity involved in these tensions and their influence on Learning Opportunities developed there.

Roger has intellectual prestige among the classmates for his knowledge assimilation capacity as regards concepts of Physics. He makes a point of expressing to his colleagues these abilities. For him Physics appears as intellectual activity upscale own geniuses. He strives to demonstrate autonomy in the Physics lessons, but also infringes the classroom rules and always disperses the attention of his colleagues. He does its best to be recognized as "brilliant student" among peers and some teachers, personifies the western hegemonic masculinity.

Nicholas faces deep difficulties and resistances in his relation with school. He has low achievement in Physics and little participation in the classroom tasks. For him, physics is a discipline of prestigious outside their universe of possibilities. It has characteristics of masculinity protest.

Thales has good academic performance in Physics. Tales show affinity with both the intellectual elaboration of ideas and with their systematization and improvement. He is disciplined, concentrated and engaged to school tasks, expresses empathy with physics as a rational activity guided by systematic procedures. He presents characteristics of masculinity of men of reason.

We analysed interactions between the three during a student-centred activity designed to pass on an idea of how a scientific team works. The activity challenges students to solve open-ended problems, thus requiring them to take decisions, investigate phenomena and establish some cooperation among themselves. The dynamics of the activity simulates an atmosphere of game and competition alternating moments of work in group with moment of collective discussions mediated by the teacher involving all groups.

RESULTS

The hegemonic masculinity appeared around the relationships that occurred within the group examined at the first class. Since the group began to work there was a tension between the domineering attitude of Roger and the immediate engagement of Nicholas and Thales on the activity. Roger tried to impose the leadership of the group and to subordinate the colleagues at his will, trying to sabotage the activity by disqualifying it as school task and diverting the attention of his colleagues. Thales and Nicholas were instigated by the activity, they insisted on carrying out the investigation and to cooperate between themselves to overcome the challenges posed by the teacher seeking the collaboration of Roger. The investigation and discovery of the phenomenon consisted of *Learning Opportunities* that two colleagues wanted to share.

Roger challenged the rules of the classroom and tried to impose its control and authority over their colleagues. Nicholas found it difficult to concentrate on investigation in the face of provocations from Roger. He reacted with a certain aggressiveness to calls for Roger (in some way he responded when provoked and was controlled by Roger), but at the same time, trying to convince him to engage in investigation.

Most of the time, Nicholas sought to remain engaged in the activity, but as he had no prospects for academic success at that school, that made him likely to seek prestige among colleagues by confronting the classroom rules and by challenging authority. He wanted to engage with the activity at different times, but Roger's influence dispersed him.

The relationship of Roger with Nicholas and Tales denoted hierarchical position, individualism and dominating rationality. Roger advised the group only on issues that required "intellectual work", but refused to make measurements or notes. He denied his colleagues' knowledge of and their explicit desire to engage in investigation, thus sharing *Learning Opportunities*.

In our interpretation, the authority granted to Roger occurred around their intellectual prestige, as evidenced by the domain that showed in relation to scientific knowledge. It was a rational strategy of the group to stay in front of the other groups in investigation. Evidence of this is the fact that the explanation developed by Roger to analyze the phenomenon was accepted with enthusiasm by Nicholas, since they could be at an advantage over other groups. This reinforced the arrogance and individualism of Roger that preferred to disregard the comments made by Nicholas and Tales inhibiting them, with explanations that take into account only their view and supposed prior knowledge.

Roger's relationship with his colleagues showed two patterns of masculinity. The first was the hegemonic standard of knowledge and rationality that led him to assist the group only on issues that required "intellectual work", but refused to make measurements or notes. However, he did not respect the opinions of their colleagues and their explicit desire to engage in investigation sharing *Learning Opportunities*, as they did the other groups. This compromised their performance in investigation and left the group at a disadvantage compared to others.

The second model of masculinity is close to what Connell (1995, 2000) identifies as "protest masculinity" linked to "complicity" between Roger and Nicholas (Connell, 1995). "Protest masculinity" is a way to gain prestige among peers, scoring differences and get pleasure by the confrontation with the rules and challenge authority. Nicholas had no other sources for academic success at that school, this made him likely to resort to "protest masculinity" as a means to gain prestige among colleagues. He wanted to engage with the activity at various times, but the influence of the demoted Roger. There was complicity between the two about the jokes and games in class. in this case, the trend is highlighted by Roger to challenge the rules in the room lesson and deter his group and other groups to focus on the task. Even when it was curious or intrigued by the phenomenon that Roger tried to shine the tasks was not to challenge him.

Thales sought alternatives for the group could carry out the activity; he made use of the rationality of Roger and the aid of Nicholas to carry out tasks without getting in conflict with them. That was his strategy to stay in investigation, in the running of the competition and develop new *Learning Opportunities*.

The collective discussions with the whole class allowed the socialization of investigation strategies and findings of the groups leaving all of them always at the same level, with the completion of a task that was available to everyone. The teacher's interventions in the groups encouraged them to organize more collaboratively and to share tasks. Both in the intervention in the small groups, as well as in collective discussions, the teacher tried to manage the tensions generated by the participation of boys like Roger inhibiting actions and relations of domination in favour of interactions guided by cooperation and dialogue with the ideas of colleagues.

CONCLUSIONS

We used interactional analysis to problematize configurations of masculinity and their influence on the elaboration of *Learning Opportunities* in a group of boys in a Physics classroom. The *Learning Opportunities* were focused in the living experience of the discovery process, the search for evidence to prove or rule out forecasts and assumptions, the discipline to carry out measures, the negotiation of expectations and the organization of a work plan.

By resorting to challenging situations, such as open investigation activities in the classroom we must keep in mind some care. Important dimensions of the training of lads are put at risk when - in a discipline such as physics - they are guided by Western hegemonic standard of masculinity, that legitimizes and values, for example, competition, an ultra-rational objectivity, individualism, emotional distance , domination, etc..

In this work, we gave special attention to the fact that a guy with a strong tendency towards individualism and great need to show himself superior enforced anti-school attitudes and indiscipline in another pupil with problems in school. However, tensions between different forms of masculinity were relieved when those involved were instigated by the activities in the classroom and saw possibilities of growth and success in the face of others colleagues or other masculinities. The collective discussions and the teacher's interventions gave priority to *Learning Opportunities* that forced configurations of masculinity based on partnership relations among group members.

HOW ARE HIGH SCHOOL STUDENTS' EPISTEMOLOGICAL BELIEFS RELATED TO THEIR GOAL ORIENTATIONS?

Cansel Kadioglu[1], Esen Uzuntiryaki[2], Yesim Capa Aydin[2]
[1]Gaziosmanpasa University, Turkey
[2]Middle East Technical University, Turkey

Abstract: Literature reveals that epistemological beliefs and goal orientations affect students' strategy use and learning in turn. When students set mastery goals they are expected to use more advance strategies such as elaboration and critical thinking and develop conceptual understanding. In order to support meaningful learning, the relationship between epistemological beliefs and goal orientations needed to be defined clearly. This study was conducted to examine the relationship between two sets of variables: epistemological belief (the belief that learning depends on effort, the belief that learning depends on ability, and the belief that truth can change) and goal orientation (performance approach, performance avoidance, mastery approach, and mastery avoidance). Epistemological beliefs were assessed with the Epistemological Belief Questionnaire while goal orientations were measured using the Goal Orientation Scale. The data were collected from 950 Turkish high school students participating chemistry classes. Results of canonical correlation analysis revealed one significant canonical variate pair (R_c^2 =. 37). The beliefs that learning depends on effort and ability were associated with performance approach and mastery approach goals.

Keywords: Epistemological beliefs, 2 x 2 achievement goal framework, chemistry, science education, canonical correlation analysis

INTRODUCTION

The purpose of this study was to examine the relationship between Turkish high school students' epistemological beliefs and goal orientations in chemistry courses. Recent studies revealed that students' epistemological beliefs are effective while they are setting learning goals (Ozkal, Tekkaya, Cakiroglu, & Sungur, 2009; Chen & Pajares, 2010). Students' who possess more sophisticated epistemological beliefs tend to set mastery type of goals more frequently and expected to use self-regulatory strategies more effectively (Ozkal et al., 2009; Chen & Pajares, 2010).

Achievement Goal Theory

Achievement Goal Theory explains the reasons for learning. Initial studies were guided by dichotomous (mastery versus performance goals) (Pintrich & DeGroot, 1990) or trichotomous frameworks (mastery, performance-approach and performance-avoidance goals) (Elliot & Church, 1997). Recently, Elliot and McGregor (2001) propsed a 2 x 2 achievement goal framework: performance approach, performance avoidance, mastery approach, and mastery avoidance. They developed a new instrument reflecting four goal orientation types and found empirical evidence. Mastery approach goals emphasize mastering the task or learning the task for its own sake and use achievement standards such as progress in the task or deep understanding of the topic. Mastery avoidance goals were defined as avoiding misunderstanding or not learning and students set not being wrong as a standard for learning. On the other hand, performance approach goals focus on doing better than others in a task and getting better grates than others is more important for learners. Lastly, students setting performance avoidance type of goals give importance to not looking stupid compared to others and not getting worse grades than them. Although the validity of 2 x 2 achievement goal framework is still discussed, a few studies are providing empirical support (Bartels & Magun-Jackson, 2009; Conroy & Elliot, 2004; Sungur & Senler, 2009). The present study was guided by the 2 x 2 achievement goal framework.

Epistemological Beliefs

Epistemology as a discipline tries to explain individuals' beliefs about the nature of knowledge and knowing. It is "an area of philosophy concerned with the nature and justification of human knowledge" (p.88, Hofer & Pintrich, 1997). The present study was guided by multidimensional models which suggest that epistemological beliefs are independent; in other words, students can hold more sophisticated beliefs in one dimension and more naive beliefs in another (Schommer, 1990; Hammer & Elby, 2002). In addition, in this study students' epistemological beliefs were defined based on the dimensions in the Schommer's questionnaire (Schommer, 1990) which reflects students' beliefs about knowledge and learning.

The Relationship between Students' Epistemological Beliefs and Goal Orientations

Recently researchers have been sought for the relationship between students' epistemological beliefs and goal orientation types and tried to understand mediating factors in learning. Their attempts to understand whether students possessing different epistemological beliefs tended to set specific type of goals and revealed more condense models (Ozkal et al., 2009; Chen & Pajares, 2010). For example, Chen and Pajares (2010) found that students holding more sophisticated epistemological beliefs tended to set task (mastery) goals while students with naïve perspective tended to set performance goals. They also found that students' motivational goals orientations affected their science achievement indirectly through self-efficacy.

Lately the effect of students' epistemological beliefs and goal orientations on different learning outcomes such as strategy use and self-efficacy beliefs has been investigated in the literature. Students using mastery goals are believed to employ higher order learning strategies such as elaboration more frequently. In order to develop classroom environments that support conceptual understanding and in turn increase achievement, initially the relationship between epistemological beliefs and goal orientations should be understood.

Research Question

The following research question guided the study: How strongly are Turkish high school students' epistemological belief variables related to their goal orientation types for chemistry context?

METHODOLOGY

Subjects of the Study

Totally 950 high school students attending chemistry courses participated in the present study. Of 950 students, 356 students (187 females, 169 males) were ninth graders, 323 (173 females, 148 males, and two nonrespondents) were tenth graders, and 271 (157 females, 112 males, and two nonrespondents) were eleventh graders.

Instruments

The Epistemological Belief Questionnaire (EBQ) developed by Schommer (1990) and adapted to Turkish culture by Deryakulu and Buyukozturk (2002) was administered to students to measure their epistemological beliefs. The Turkish version of the scale, showed a three dimensional factor structure: the belief of learning depends on effort (mentioned as *effort* throughout this study), the belief of learning depends on ability (mentioned as *ability*), and the belief that truth can change (mentioned as *truth*). In the present study, Confirmatory Factor Analysis (CFA) using LISREL 8.30 for Windows (Jöreskog & Sörbom, 1993) revealed the fit indices (.069 for Root Mean Square Error of Approximation (RMSEA), .073 for the Standardized Root Mean Square Residual (SRMR), .69 for Non-Normed Fit Index (NNFI) and .72 for Comparative Fit Index (CFI) were within acceptable limits, except for NNFI and CFI (Kline, 1998). The Cronbach alpha coefficients ranged from .48 to .71. Although the reliability coefficients were low, these values were close to the values reported in the literature (Schommer, 1993; Deryakulu & Buyukozturk, 2002).

The Goal Orientation Scale developed by Elliot and McGregor (2001) and translated to Turkish culture by Senler and Sungur (2007) was administered to determine the type of goals students pursue while studying for chemistry course. The instrument included four subscales: mastery approach, mastery avoidance, performance approach, and performance avoidance. Confirmatory Factor Analysis (CFA) was performed to test factorial validity of the scale. Findings indicated a good model fit with the following fit indices: RMSEA = .079, SRMR = .059, CFI = .95, and NNFI = .93 (Kline, 1998). The Cronbach alpha coefficients were found between .68 and .76.

RESULTS

The means and standard deviations for each factor, and bivariate correlations between the variables in each variable set and between the variable sets were presented in Table 1. High values for the mean scores indicated that students possess more sophisticated epistemological beliefs use that goal orientation type more frequently.

Table 1

Means, standard deviations, and bivariate correlations among measured variables in two variable sets.

Subscale	1	2	3	4	5	6	7
1. Effort	1.00						
2. Unchanging Truth	-.19**	1.00					
3. Ability	.17**	.17**	1.00				
4. Performance approach	.19**	-.19**	-.02	1.00			
5. Performance avoidance	.03	-.22**	-.14**	.49**	1.00		
6. Mastery approach	.32**	-.13**	.18**	.33**	.10**	1.00	
7. Mastery avoidance	.05	-.17**	-.13**	.25**	.33**	.21**	1.00
Mean	3.92	2.83	3.53	3.72	3.24	4.19	3.21
Sta. Dev.	.39	.51	.66	.97	1.06	.80	.97

**. Correlation is significant at the .01 level (2-tailed).

The canonical correlation analysis (CCA) was conducted to test the relationship between two variable sets (epistemological belief and goal orientation variables). Results of CCA revealed three canonical variate pairs; however, only the first canonical variate pair was found to be significant. The canonical correlation coefficient between two canonical variates was found to be .37 accounting for 14% of overlapping variance.

Table 2 summarizes the correlations, standardized canonical coefficients, canonical correlations, percentage of variance, and redundancies between epistemological belief and goal orientation variables for the first canonical variate pair. Explained variance by epistemological belief and by goal orientation were 29% and 39%, respectively. When the canonical loadings were examined, the values greater than .40 were accepted as meaningful (Weiss, 1972). Effort and ability positively correlated with the first canonical variate while only the approach type of goals made significant contribution to the second canonical variate. Effort accounted for the highest percentage of variance with a loading of .90, whereas mastery approach goals has the highest with a value of r=.95. Truth and avoidance type goals did not have any significant contribution. On the other hand, the amount of variance in the canonical variate explained by the other canonical variate (called the redundancy index) was 4% for the epistemological belief and 6% for the goal orientation.

Table 2

Correlations, standardized canonical coefficients, canonical correlations, percentage of variance and redundancies between epistemological belief and goal orientation variables

	First Canonical Variate	
	Correlations	Coefficients
Epistemological beliefs variables		
Effort	0.90	0.78
Unchanging Truth	-0.30	-0.22
Ability	0.53	0.44
Percentage of variance	0.29	
Redundancy	0.04	
Goal orientation variables		
Performance approach	0.49	0.31
Performance avoidance	0.03	-0.16
Mastery approach	0.95	0.90
Mastery avoidance	0.04	-0.17
Percentage of variance	0.39	
Redundancy	0.06	
Canonical correlation	0.37	

DISCUSSION AND IMPLICATIONS

In this study, the relationship between Turkish high school students' epistemological beliefs and goal orientations was investigated. The results revealed that the canonical correlation between two variable sets accounted for 14% of the overlapping variance. In addition, the goal orientation variate accounted for higher variance (39%) than the epistemological belief variate (29 %). The beliefs that learning depends on effort and ability were associated with performance approach and mastery approach goals. This indicated that students who possessed more sophisticated epistemological beliefs, set approach type of goals more frequently while studying for chemistry course. Accordingly, explicit instruction of nature of science can help students develop more sophisticated beliefs and increase chemistry achievement in turn.

Mastery approach goals found to be explaining the highest variance of the canonical variate goal orientation with a canonical correlation value of r=.95. This result is parallel with the previous studies (Ozkal et al., 2009; Chen & Pajares, 2010). However, performance approach goals were also found to be positively correlated to epistemological beliefs which mean that students holding more sophisticated epistemological beliefs tend to set these goals as well as mastery goals. In Turkey, students are required to take nationwide exams in transition to a higher education level. Taking high scores from these exams are important to attend high reputation schools. Therefore, students might set performance goals for themselves to be more successful than other students.

This study has implications for educators and future research. Teachers should emphasize meaningful learning and help students develop sophisticated epistemological views. This study focused more on the relations between two variable sets in chemistry course for high school students in Turkish context. In the further studies, structural equation models can be employed to test the direct and indirect paths between these variables, and their relationship to academic achievement.

Abstract: This study focuses on the investigation of the relationship among the learning outcomes, the emotional experiences and the social interactions of students in a distance education setting in Greece. The present study involved 153 postgraduate and undergraduate students enrolled in distance learning courses at the Hellenic Open University. Questionnaires were used as a data collection instrument for the survey and the data were analyzed using Statistical Package for Social Sciences (SPSS). The analysis of the data gathered provided evidence regarding the correlation among the three variables used in our research. Findings indicated that the learning outcomes have little or no relation either to the emotions of students or to the social climate. In addition, the results revealed that the social climate and the emotional experiences of students are closely related.

Keywords: distance learning; cognitive development; emotions; collaborative learning

INTRODUCTION

Within only a few years, distance education emerged as a new philosophy for knowledge transmission offering new and flexible learning opportunities that overcome the restrictions of time and space. Over the years, the demand for distance education courses has grown exponentially as people seek for new and flexible ways to update their skills while they meet the demands of their busy lifestyles.

Rationale

Distance education is "a practice in which the learner and the instructor are separated in space and/or time" (Saba, 2005:262). Distance learning programs are designed to be carried out by technology that allows learners to attend online lessons according to their schedule, have access to the educational material and communicate with the instructor and the other learners.

Although distance education provides the flexibility of combining studies with work and family obligations, it demands more responsibility from the learners. Distance learners are independent, autonomous, self-motivated and managers of their own time (Berge, 2007; Shih et al., 2008). They built their knowledge on their own while the use of technology enhances their critical thinking, research and problem-solving skills (Bedard & Knox-Pipes, 2006; Berge, 2007; Lunney et al., 2008).

For an effective learning environment in both distance and traditional settings social interaction is an essential component. As Pauls (2003:3) argued "it is not the location of education that determines the effectiveness, but the amount on transaction between the learner and the instructor".

Learning is a social process and therefore, the development of social climate is a key factor for high levels of academic performance (Koh & Hill, 2009; Kreijns et al., 2004). Learner-learner and teacher-learner interaction will allow the exchange of information, ideas and collaborative learning. Additionally, distance education programs must meet the requirements of today's workplace for highly skilled personnel with communication and collaboration skills, problem-solving and decision making skills. Although social interaction is a significant area for education, it's affect on learning in distance education settings has been neglected by research (Oren et al, 2002).

Another basic factor related to the academic performance of students is emotions. Due to the lack of physical presence students experience emotions of isolation and lack of community sense in distance learning settings. Until recently, the role of emotions and their impact on the learning performance of students has been a neglected topic to the research agenda, with the exception of test anxiety (Pekrun, 2005). However, in the last few years, the research has highlighted that emotions are an integral part of education and affect student's motivation and engagement in the learning process (O' Regan, 2003; Op't Eynde & Turner, 2006; Wosnitza & Volet, 2005).

In Greece, research in the field of distance education developed substantially with the foundation of the Hellenic Open University that dates back to 1992. Although several subjects have been examined including student's perceptions about distance education, student-dropout and economical issues, there is limited theoretical framework as the majority of the published research focuses on the evaluation of the educational material (Giosos et al., 2008).

The aim of the current study was to investigate whether student's emotional experiences and the development of social climate in the distance education setting of the HOU have an impact on student's learning outcomes.

METHODOLOGY

Objectives of the study and research question

The main purpose of this study was to investigate the emotional experiences of students and relate them to the social climate and to the learning outcomes. Student learning outcomes (SLO) are defined in terms of knowledge and skills gained as a result of participating in a particular set of educational experiences (Montgomery College, 2009). The aim of this study was to answer the following research question:

What is the relationship between the learning outcomes, the emotion of students and the social climate in the distance education environment of the Hellenic Open University?

Procedure

A questionnaire based on the Learner Questionnaire (LQ), which was used by the Australian Council for Educational Research-ACER, was designed as an instrument for gathering data on students' perceptions relative to the distance education provided by the HOU. The aim of the questionnaire was to investigate cognitive, emotional and social aspects and the relationship among them.

The questionnaire was divided into two sections. The first section consisted of closed quantitative Likert-type questions. The items were ranked according to a 1 to 5 Likert scale (strongly agree, agree, neutral, disagree, and strongly disagree). The second part of the questionnaire aimed to deal with demographic data (e.g. gender, age, year of study, program of study). The instrument was administered face-to-face to the distance learners during the face-to-face meetings.

Participants

The participants of this study consisted of 153 postgraduate and undergraduate students of the HOU. Of the participants 57% (n=87) were female and 43% (n=66) were male. The participants' age ranged to three categories: ninety five students were over 33, forty nine students were between 28 and 32 and nine students were between 23 and 27.

Results

Data gathered from the questionnaire were organized and analyzed using Statistical Package for Social Sciences-SPSS. Since we presumed correlated factors, a direct oblimin rotation was selected and five factors were extracted. These five factors explain 50% of the total variance, which is a high percentage for social science standards. Therefore we can assume that the extracted factors successfully summarize the 36 variables used in the analysis. The five factors that were extracted were:

1. Satisfaction with the trainers and the lessons
2. Anxiety, insecurity and boredom
3. Gain of skills and knowledge
4. Poor facilities and organization and
5. Generic disappointment

Examining the correlations between the five factors extracted can give an indication of the relationship between the emotions of the students and the skills they gained (see figure 1).

	Factor 1: Satisfaction with the trainers and the lessons	Factor 2: Anxiety, insecurity, boredom	Factor 3: Gain of skills and knowledge	Factor 4: Poor facilities and organisation	Factor 5: Generic disappointment
Factor 1: Satisfaction with the trainers and the lessons	1	0.021	0.111	-0.302**	-0.421**
Factor 2: Anxiety, insecurity, boredom	0.021	1	-0.044	-0.034	-0.062
Factor 3: Gain of skills and knowledge	0.111	-0.044	1	-0.120	-0.155
Factor 4: Poor facilities and organisation	-0.302**	-0.034	-0.120	1	0.250**
Factor 5: Generic disap-pointment	-0.421**	-0.062	-0.155	0.250**	1

**. Correlation is significant at the 0.01 level (2-tailed)

Fig1: Pearson correlations among the five factors

As showed in figure 1 the third factor, which is an expression of the skills and knowledge gained, is not correlated to any kind of emotions. On the other hand, we do see some significant correlations between the different emotions: it seems that those who are satisfied with the trainers and the lessons are less likely to express a generic feeling of disappointment (-0.421) or to claim that the facilities and organization of the HOU are poor (-0.302). The results of the survey also revealed that there is a positive correlation between factors four and five (0.250), indicating that the feeling of generic disappointment is caused partially from the poor facilities and organization of the HOU.

According to figure 2 the results indicated that the most significant problem respondents faced when doing group work was the lack of time, nearly 55%, followed by the lack of a sense of community (33%) and by difficulties in communication (25%). What is interesting is that 8.5% mentioned that they have never done group work before.

What is most interesting about the problems encountered during team work is how they are related to the five factors that were extracted from the factor analysis (see figure 2).

Problems while doing team work:		%	Factor 1: Satisfaction with the trainers and the lessons	Factor 2: Anxiety, insecurity, boredom	Factor 3: Gain of skills and knowledge	Factor 4: Poor facilities and organisation	Factor 5: Generic disappointment
Difficulty in understanding goals/objectives	No	84.3	0.09	-0.02	0.03	-0.06	-0.09

Others (I have never done group work)	No	91.5	-0.03	0.00	0.00	0.00	0.05
	Yes	8.5	**0.29**	-0.03	0.09	0.05	**-0.51**

Fig2: Problems during group work and factor means.

Three out of four factors that are related to emotions are significantly related to many of the problems encountered during group work. A positive answer in one of the problems is less likely if the responder is satisfied with the trainers and the lessons and more likely if he or she expresses a feeling of generic disappointment or feels that the facilities and organization of the HOU are poor. The feelings of anxiety, insecurity and boredom are related to only two of the problems mentioned. What is interesting is that those who mention that have never done group work are satisfied with the trainers and the lessons, and are less likely to express a feeling of generic disappointment. The reason for that may be because the responders view it more as a personal challenge than as a real problem.

The most interesting finding showed in figure 2 is that the learning outcomes have almost no relation to the problems experienced during team work. We find factor means of some importance only for two of the problems, but these means are not very high and one of them has the opposite direction of what was expected (the lack of leadership is positively related with the skills gained). Therefore, if we assume that the experience of problems during team work indicates a poor social environment, it seems that this environment has no impact on the learning outcomes.

Finally, according to the data there is definitely a strong relation between positive emotions and the development of a social climate and vice versa, the learning outcomes are related to none of them.

CONCLUSION

This research has sought to answer whether there is the relationship among the learning outcomes, the emotional experiences of students and the social climate that develops in the distance education environment of the HOU. The data gathered from the questionnaire revealed that although there is a relationship between emotions and social interaction, none of the two variables influence the skills and knowledge acquired from the students.

There are some possible explanations for the outcomes of this research. Tzoutza's (2009) research at the HOU revealed that emotional support and encouragement from the teacher is not of primary importance for the students. Students at the HOU are more interested in academic support in order to fulfill their obligations on time. It seems that the students at the HOU control their emotional reactions and are committed to their goals, which according to Järvenoja and Järvelä (2005) is called volition.

Moreover, research by Wosnitza and Volet (2005) reported that exploring emotions in online education is difficult since students hide their feelings. Participants' unwillingness to disclose their feelings is a serious limitation when investigating emotions. There is a possibility that the participants of this study hid their true feelings about distance education and the mid-point at the Likert scale made it easier for them. Furthermore, research on emotional aspects in the Greek educational context has been neglected and respondents were unfamiliar with questions evaluating their emotional state.

The results of the research also indicated that the HOU does not promote opportunities for social interactions and group work something that Papavasiliou-Alexiou and Dimitropoulos (2009) also confirm. Additionally, most of the participants were over 30 with family, work and social obligations. It is possible that due to the limited time they have at their disposal for their studies they have poor social interactions with the other students.

The results revealed that there are significant differences relative to the gender and the age of the participants. Women experience emotions of anxiety, insecurity and boredom at higher levels than men. Finally, the participants aged from 23 to 27 were more disappointed with the trainers, the facilities and the knowledge and skills they gained that those aged from 33+.

DO SCIENCE RESEARCH APPRENTICESHIPS ENHANCE PUPILS' INTEREST IN SCIENCE?

Suzanne Kapelari[1], Elisabeth Carli[1] and Anna Oberrauch[1]
[1]Institute of Botany, Plant Science Education Center
University Innsbruck, Austria

Abstract: Science reforms call on schools to engage students in doing science rather than simply studying it. Research funding associations ask scientists to include activities into their research projects to demonstrate broader impacts. Student-Scientists Partnerships (SSP) are becoming more and more popular. However we only know little about what benefits both partners derive from these interactions. Science learning theory tells us that how children learn is partly determined by what they already know including the schemes and perspectives they bring to a new situation. In SSPs pupils are asked to participate in a knowledge context far beyond what they have experienced so far.
This paper is reporting on a broader impact project with high school students in the research field of ecology and climate change. While several studies on SSP programs demonstrate rather positive results our study shows that student´s content knowledge development is limited. Understanding the bigger picture was a serious challenge. Only little positive effect is observed on student's interest in science in general and on scientific topics in particular. Based on the theory of the "Four Phase Model of Interest Development" we suggest that in SSP´s students may experience feelings of autonomy and competence to a lesser extent than proposed. We finally conclude that further attempts have to be made to determine the reported empirical established set of benefits generated by SSP programs.

Keywords: student-scientist partnership; secondary education; interest in science; inquiry; ecology

BACKGROUND

More and more research funding associations ask scientists to include activities into their research projects to demonstrate broader impacts on science and society (Lok, 2010). Student-scientist partnerships (SSP) are becoming more and more popular. This study will report on a SSP´s project established through an ambitious program named "Sparkling Science". The program was launched by the Austrian Federal Ministry of Science and Research in 2008. Starting point was an increasing recruitment problem in some areas of science and technical sciences as well as high university dropout rates. Inviting pupils and their teachers to participate in authentic research projects is expected to enhance pupil's interest in science and scientific careers. This may help them to make a better choice for their university studies. Sparkling Science research projects are therefore not only focussing on publishable scientific outcomes but pupils should be included in reasonable research tasks. Students not only collect data but contribute to final publications to support learning gains on higher order outcomes (Ryder & Leach. 1999). This paper refers to a Sparkling Science project named "*Top-Klima-Science - Hydrologic balance and global change: future outlook for mountain areas in the face of changes in land use and climate*". The research focus of this project was to understand the impact of land use and climate change on the hydrologic balance in mountain areas as precisely as possible. Scientist at the Institute of Ecology at the University of Innsbruck, the European Academy Bolzano, Italy and teachers and their pupils aged 15 to 20 years from the higher agriculture school HLFS Kematen in Tyrol were partners in this two years lasting scientific endeavour.

THEORETICAL FRAMEWORK

Krapp (2005) argued that a person is always in interaction with an object or topic and this needs to be considered when analyzing human activities or development. This interaction is characterized by content, activity and context. The Person object theory of interest suggests to consider a cognitive and emotional regulation system that is responsible for both the formation of interest-related intentions and the evaluative feedback during concrete person object interactions. A basic needs system has to be understood as working holistically. The three essential “basic needs” are: social relatedness which is described as feeling of being connected and accepted by significant others, autonomy which is specified as feeling independent from undesired external and internal pressures and competence which leads to efficacious and attained valued outcomes. When students are asked about their feelings during a past sequence of learning activities they normally refer spontaneously to experiences that are obviously related to the system of basic needs.

In addition science learning theory tells us that the level of a person’s interest has not only a powerful influence on students learning (Renninger et al., 2002) but interest predicts college students choice of academic major (Harackiewicz et al., 2002). The Four Phase Model of Interest Development describes the development and deepening of learner’s interest as an ongoing process from triggered situational interest and its maintenance to emerging and finally well developed individual interest. In this model feeling of competence, autonomy and social relatedness as well as differentiated knowledge structures contribute to the interest development in all individuals (Hidi & Renninger 2006). In terms of a constructivist perspective we need to consider that what and how people learn is partly determined by what they already know including the schemes and perspectives they bring to a new situation. Pre-existing concepts about natural phenomenon’s either hinder or mediate students reasoning ability and are essential for understanding a particular scientific context (Strike &Posner, 1992, Duit & Treagust, 2003). However n this SSP´s pupils are asked to participate in a knowledge context far beyond what they have experienced already and the central tension, mentioned by Sadler et al., (2010) is inherent to SSP programs: “*scientists seek high quality data and teachers and students expect high quality learning experiences”*(p. 250). However research shows that science apprenticeships are successful in various ways but Sadler et al (2010) concludes “*that researchers have over-relied on the self-reports of participants as the basis for claims made in support of these programs*” (p.252).

PURPOSE

The research question addressed in this study was: Is there a proof for the notion that this particular Student Scientist Partnerships (SSP´s) actually “enhances student’s interest in science”.

CONTEXT AND METHODS

50 Students, aged 18 to 20, participated in this study (37 female and 13 male). A multi perspective approach based on achievement tests, questionnaires and interviews in a pre and post test design was applied. Closed questions were asked in questionnaires to learn more about pupils’ interest in and attitude towards science. These questions were based on

validated questions addresses in the OECD PISA 2006 study (PISA 2007) and the ROSE study (Elster 2007). Reconstruction of pre existing concepts was investigated via open questions students answered in a paper and pencil test as well as via individual interviews. Focus group interviews were conducted with 12 students (6 boy and 6 girls) to learn about their interest development in more detail. Students were selected based on their level of interest presented in the pre-test (in each case four students with a high, moderate and a low interest in science). Interviews were transcribed and analysed with “Qualitative Content Analysis” techniques and a score was calculated for interest as well as content knowledge development (Mayring 2008).

RESULTS

Questionnaire results revealed that students show a higher than average level of interest in most scientific topics when they entered the project. This interest more or less does not change until the end of the project. In addition student’s attitude towards science does not increase significantly at time. However there is a tendency that the apprenticeship program helped students to clarify their view about scientific studies. Many students reported that participating in the SSP had no impact on their currently held career plans. Student´s concept development was limited although many of them did achieve a better understanding of single scientific facts. Understanding the bigger picture was a serious challenge only a view of them managed to cope with. But most students reported that it is very important for them to understand what the research project is all about. Students also expected the research project to lead to clear answers to research questions and did not consider research as a long lasting process.

Focus group interview with 12 students selected according to their pre project interest in science in general and the research topic in particular revealed a much more differentiated picture. Fig.1 shows that students (S1, S2 and S5) who demonstrate an increase in interest appreciated a high level of competence, autonomy and personal relevance. Those students (S3, S4 and S12) who revealed a decrease of interest indicated that the project had no personal relevance to them. Although S3 and S4 scored high in interest at the beginning their interest obviously dropped until the end of the project. Nearly all students in Group B had in common that they did not appreciate a feeling of autonomy and they evaluated the research topic and science in general as not personally relevant.

Those students who displayed that basic needs like the feeling of competence, autonomy and social relatedness where not fulfilled are more likely to experience a decrease of interest in science in general as well as in the research topic in particular. On the contrary those who experience autonomy, competence and social integration are more likely to show an increase of interest through a longer lasting student scientist apprenticeship experience. Cognitive understanding of the research content seems to have an influence on the experience of autonomy and competence.

While students understanding of the context of the research project was limited cognitive understanding of given sub concepts related to the research question was moderate. However students self perception about understanding the context appeared to be better than exam results revealed.

Student	Appreciation of competence	Appreciation of autonomy	Social embedding	Personal relevance , fruitfulness	Cognitive understanding (Context of the research)	Cognitive understanding of details	Increase of conceptual understanding	NOS
Group A: Increase of interest (≥ +5 Score-points)								
S1	H	H	H	H	M	H	L	H
S2	H	H	M	H	M	H	M	M
S5	H	H	H	H	L	M	M	M
Group B: Interest remained constant (≤ -5 to ≤ + 4 Score-points)								
S6	M	L	M	L	L	M	M	M
S7	M	L	M	M	L	M	H	L
S8	M	L	M	N	L	M	H	L
S9	M	L	H	M	L	M	M	L
S10	N	L	M	L	L	L	L	L
S11	M	M	M	M	L	H	H	L
Group C: Decrease of Interest (≥ - 6 Score points)								
S3	L	L	M	L	L	H	H	M
S4	H	M	M	L	M	H	H	H
S12	L	L	M	L	L	L	L	L

Fig.1. Table of Students development: qualitative content analysis of focus group interviews based on a coding scheme (Mayring 2008) was developed to analyse changes in student's interest. Student S1-4 entered the project showing a high interest in science in general and in the research topic in particular. Students 5-8 showed a medium level of interest and students 9-12 a low level of interest at the beginning of the project. H = high, M = medium, L= Low range of score points.

DISSCUSSION

While several studies on SSP programs report a positive increase in content knowledge (Brown & Melear 2007, Hunter et al 2007) our study only revealed a limited growth of conceptual development, far more limited than teachers and scientists had expected. This might be caused by the fact that students did not have the complex theoretical background needed to understand research work. Although researchers spent a reasonable amount of time on explaining their research topic in great detail not enough time was given to students to become consciously aware of their own conceptions, share personal concepts within the learning community or test and compare personal conceptions with scientific models and explanations for plausibility (Ebenezer et al 2009). As far as interest development is concerned empirical results clearly show that interest-based learning is related to self-regulated learning. The quality of the learning outcomes, a differentiated knowledge and basic needs like the feeling of competence, autonomy and relatedness play a crucial role. Students who did not understand the scientific context may not experience competence and autonomy in a SSP programs and therefore may not show an increase in their interest in science in general or in scientific careers in particular. Various studies show that SSPs promote career aspirations in the sciences (Russel et al 2007, Lopatto 2004) but these results may be based on the fact that many studies focus on SSP programs students choose voluntarily whereas students in this study the students had not been asked whether they want to participate but their whole class was enrolled by an interested teacher. Only a view of the students reported to be interest in a scientific career at the beginning of the program which did not change in the course of time. Many students felt disappointed about the fact that their research did not yield a practical result. They expected clear answers to asked questions and wanted to draw consistent consequences out of their results. This judging shows us that even after spending quite some time in a research environment, pupils did not acquire an understanding of the classical meaning of science.

IMPLICATIONS

This study shows that student's interest development is influence by many aspects that need to be considered when asking young people to enter a student scientist's partnership. To assume that the mere invitation of pupils and their teachers to participate in authentic research will automatically enhance pupil's interest in science and scientific careers and may help them to make a better choice for their university carrier lacks evidence. We conclude that attempts to determine an empirical established set of benefits generated by SSP programs are still in critical needs of profound analyses. Further studies are necessary to clarify the fact whether the student interest is increase by SSPs or not.

AN EXAMINATION OF GENDER DIFFERENCE IN MIDDLE SCHOOL STUDENTS'SCIENCE SELF-EFFICACY AND ITS SOURCES

Dekant Kiran[1,3] and Semra Sungur[2]
[1]Gazi Osman Paşa University, Faculty of Education, Department of Elementary Education, Tokat, 60150, Turkey
[2]Middle East Technical University, Faculty of Education, the Department of Elementary Education, Ankara, 06531, Turkey
[3]PhD Student at Middle East Technical University

Abstract: This study aimed at examining the differences between boys and girls in terms of science self-efficacy and its sources. 1915 elementary students (905 females, 1010 males) participated in the study. The results indicated that there is not a statistically significant difference between boys and girls in terms of their science self-efficacy levels. Concerning sources of science self-efficacy, mastery experience was found to be the leading source for both boys and girls. Additionally, verbal persuasion and emotional arousal were found as significant predictors of students' science self-efficacy for both genders. On the other hand, vicarious experience did not significantly predict students' self-efficacy. Findings, in general, supported Bandura's theoretical contention regarding sources of self-efficacy.

Keywords: self-efficacy, sources, gender, mastery experience, vicarious experience

BACKGROUND

Self-efficacy was firstly introduced by Albert Bandura and defined as "beliefs in one's capabilities to organize and execute courses of action required to produce given attainments" (Bandura, 1997, p.3). Human functioning is greatly influenced by self-efficacy beliefs. Choices of activities people make, courses of actions they follow, effort expenditure and persistence are the most prominent ones (Pintrich & Schunk, 2002; Pajares, 2002). People generally select and engage in an activity that they believe it would yield desired results.

FRAMEWORK

According to Bandura self-efficacy is constructed by four principal sources which are mastery experiences, vicarious experiences, verbal persuasions and emotional arousal. Mastery experience is seen as the prominent source of efficacy beliefs (Bandura, 1986, 1997; Hoy, 2004). This is because experience is personal, or in other words authentic, which presents all endeavors to attain success. People do not judge their level of capabilities just by interpreting personal performance accomplishments. The observed actions of others or the observed performance on a task help individuals to form their efficacy beliefs. The calibration of capabilities in comparison with others is known as the vicarious experience (Usher & Pajares, 2008). The third hypothesized source of self-efficacy is verbal or social persuasions. Verbal persuasions and social support encourage individuals to persist on the task at hand and resist to aversive situations (Zeldin & Pajares, 2000). The fourth and last hypothesized source of efficacy beliefs is physiological states or emotional arousal. Stress, fatigue, mood, tension, emotion, and pain can be addressed as physiological states. They all may be influential when making judgments on self-efficacy (Hodges & Murphy, 2009). However, studies focusing on sources of self-efficacy beliefs in terms of gender differences suggested that relative contribution of the sources to the formation of students' self-efficacy may differ depending on gender. For example, working with 263 elementary school students, Usher and Pajares (2006) found that for the full sample, mastery experiences, social persuasions and physiological states were significant predictors of students' self-efficacy beliefs. Mastery experience was found to be the strongest source contributing to self-efficacy. For girls, on the other hand, social persuasions were the strongest source while mastery experience made the second strongest contribution to the self-efficacy beliefs. In contrast, for boys, vicarious and mastery experiences significantly predicted academic self-efficacy. In another study, Britner and Pajares (2006) examined sources of science self-efficacy beliefs of 319 elementary school students. The study indicated that there is not a significant mean difference between boys and girls in terms of science self-efficacy beliefs. Of the four sources, only mastery experience significantly predicted science self-efficacy for the full sample, for boys and for girls. Also mastery experience made the largest contribution of unique variance in each case (24 % for the full sample, 17 % for boys and 35 % for girls). The remaining sources have made only minor contributions to the prediction of science self-efficacy. Thus, although the research investigating sources of self-efficacy beliefs generally demonstrated that mastery experience is the leading source of students' self-efficacy beliefs, the relative contribution of each source may show differences as a function of gender.

PURPOSE

Considering the relevant literature, this study focuses on the differences between boys and girls in terms of science self-efficacy and its sources. Accordingly, the present study aims at addressing the following research question:

1. Is there a difference between boys and girls with respect to level of science self-efficacy beliefs towards science?

2. How well mastery experiences, vicarious experiences, verbal persuasions and emotional arousal predict girls' science self-efficacy beliefs?

3. How well mastery experiences, vicarious experiences, verbal persuasions and emotional arousal predict girls' science self-efficacy beliefs?

RATIONALE

Although the level of self-efficacy towards various domains (especially mathematics) was studied, science self-efficacy is studied rarely. Moreover, examination of sources of science self-efficacy is a big gap in the literature. Researchers generally studied the sources of math self-efficacy and sources of math-science career self-efficacy.

METHODS

1915 elementary 8th grade students (905 females, 1010 males) constituted the sample of the study. The Sources of Science Self-Efficacy Scale, which is a five point Likert scale and developed by Lent, Lopez and Bieschke (1991), was used to assess eight grade students' sources of science self-efficacy beliefs. For assessing level of science self-efficacy, self-efficacy sub dimension of MSLQ was used. MSLQ is a 7 point likert type scale and developed by Pintrich, Smith, Garcia, and McKeachie (1993).

RESULTS

For the first research question, to identify whether there is a significant mean difference between boys and girls in terms of level of science self-efficacy, one way ANOVA was conducted. The results indicated that there is not a significant mean difference between boys and girls at the .05 significance level (F (1, 1913) = .305, p = .58). For the second and third research questions, Multiple Linear Regression Analyses were conducted. As shown in Table 1, all sources except vicarious experience significantly predicted science self-efficacy for both genders. Of the sources, mastery experience made the largest contribution to the explained variance for both genders (sr^2 = 8 %). For girls, verbal persuasions made a relatively small contribution to the variance (sr^2 = 2 %) and emotional arousal made a minor contribution (sr^2 = 1 %). For boys, emotional arousal and verbal persuasions made nearly equal contribution to the explained variance (sr^2 = ~2 %).

TABLE 1
Regression analysis results of sources of science self-efficacy for genders

	Girls				Boys			
	Standardized Coefficients	Sig.	Correlations	sr^2	Standardized Coefficients	Sig.	Correlations	sr^2
	Beta		Part (sr)		Beta		Part (sr)	
Emotional Arousal	.17	**.004***	.07	.01	.18	**.000***	.14	.02
Mastery Experience	.80	**.000***	.28	.08	.40	**.000***	.28	.08
Verbal Persuasions	.38	**.000***	.14	.02	.20	**.000***	.15	.02
Vicarious Experience	.01	.209	.03	.00	.02	.571	.01	.00
R	.70				.69			
R^2	.49				.48			

CONCLUSIONS AND IMPLICATIONS

In line with the findings, it is concluded that there is not a statistically significant difference in terms of level of science self-efficacy between boys and girls. This finding was consistent with previous research which revealed no gender difference not only in science but also in general academic self-efficacy and in math self-efficacy (Lopez & Lent, 1992; Lent et al, 1991; Hampton & Mason, 2003). Concerning sources of science self-efficacy, mastery experience was found to be the leading source for both boys and girls. It is consistent with Bandura's theoretical consideration regarding mastery experiences. Empirical studies also support this finding (e.g. Britner & Pajares, 2006; Lopez, Lent, Brown, & Gore, 1997).

The present study also revealed verbal persuasions as significant predictor of students' science self-efficacy for both genders. For science domain, Britner & Pajares (2006) could not find verbal persuasions as a source. However, in their study, verbal persuasions were correlated with self-efficacy. Therefore, they suggest considering verbal persuasions as an antecedent of self-efficacy. They assert that social persuasions influence students' mastery experience in a positive manner. Encouragements provided by significant others bolster students' self-efficacy. However, it should be kept in mind that negative social persuasions are easily decreasing students' self-efficacy rather than increasing it with positive messages.

Concerning emotional arousal, it explained more variance in boys' science self-efficacy than that of girls. Although Britner & Pajares (2006) could not find emotional arousal as a source for science self-efficacy for both genders, Usher & Pajares (2006) found that emotional arousal is a significant source for boys' self-efficacy. In another study by Gainor & Lent (1997), emotional arousal was found as a significant source in math self-efficacy for both genders. Thus, there is a variety in findings regarding contribution of emotional arousal to students' self-efficacy.

On the other hand, in the current study, vicarious experience was not found as a significant source of self-efficacy for both genders. For science domain, it is consistent with the literature (Britner & Pajares, 2006) but, in other domains like career, math and academic self-efficacy, vicarious experiences make significant contributions to the explained variance (Lopez, Lent, Brown & Gore, 1997; Zeldin, Britner & Pajares, 2008; Usher, 2009). Although Bandura's (1997) contention regarding vicarious experiences in terms of group work and collaborative activities, in Turkish context it did not emerge as a significant source of science self-efficacy. This may be due to the competitive and normative examination system of Turkish education system. Students might have relied on their mastery experiences (performance accomplishment) in forming their self-efficacy rather than modeling their peers.

THE EFFECT OF METACONCEPTUAL TEACHING INTERVENTIONS ON STUDENTS' SELF-EFFICACY TOWARD CHEMISTRY

Zubeyde Demet Kirbulut[1] *and Omer Geban*[1]
[1]Department of Secondary School Science and Mathematics Education, Faculty of Education, Middle East Technical University, Turkey

Abstract: The purpose of this study was to examine the effectiveness of metaconceptual teaching interventions (MTI) on 10th grade students' self-efficacy toward chemistry compared to traditional instruction (TI). This study employed the matching-only pretest-posttest control group design as a type of quasi-experimental design. The sample of this study consisted of 102 10th grade students with two experimental and control groups. There were 53 students in the experimental groups and 49 students in the control groups. Students in experimental groups were instructed by MTI and students in the control groups were instructed by TI. To examine the effect of MTI on students' self-efficacy toward chemistry, high school chemistry self-efficacy scale (HCSS) was administered to the students in the experimental and control groups two weeks before the treatment and at the end of the treatment. HCSS consisted of 16 items with a 9-point scale ranging from very poorly to very well in two dimensions: chemistry self-efficacy for cognitive skills (CSCS) and self-efficacy for chemistry laboratory (SCL). Multivariate analysis of covariance was used to determine the effectiveness of two different instructional methods on students' self-efficacy. The results of the analysis revealed that there was a significant mean difference on the collective dependent variables of post-CSCS and post-SCL between experimental and control groups when the covariates were controlled.

Keywords: metacognition, states of matter, self-efficacy, MANCOVA, science education

INTRODUCTION

In the literature, there has been an increased attention on metacognition among researchers. The term "metacognition" was first introduced by Flavell in the early 1970s. Flavell (1979) defined metacognition as "knowledge and cognition about cognitive phenomena" (p. 906). Metacognition is a fuzzy concept and it lacks coherence in terms of its meaning and components (Brown, 1987). For example, Baird (1990) defined metacognition as "knowledge, awareness and control of one's own learning" (p. 184). Rickey and Stacy (2000) interpreted metacognition as "thinking about one's own thinking" (p. 915). Several researchers have proposed different models regarding components of metacognition. According to Flavell (1979), metacognition consisted of the components of "metacognitive knowledge" and "metacognitive experience". Chi (1987) identified three types of metaknowledge: meta-declarative knowledge, meta-procedural knowledge, and meta-strategies. Metacognition is widely believed to make students responsible for their learning and thus students more actively involved in the learning process (e.g., Hennessey, 1999). The continuing research into metacognition has provided that metacognitive teaching activities had positive impact on student thinking skills and conceptual understanding (e.g., Hennessey, 1999; Hewson, Beeth, & Thorley, 1998). There is also growing literature investigating the relationship between self-regulation (including metacognition) and motivational beliefs (e.g., Sungur, 2007). However, the literature lacks the studies examining the effect of metacognitive teaching activities on students' motivational beliefs. Self-efficacy is one of the important components of motivation.

Self-efficacy plays a crucial role in science education. According to social cognitive theory, Bandura (1997) defined self-efficacy as “beliefs in one’s capabilities to organize and execute courses of action required to produce given attainments” (p. 3). Self-efficacy beliefs are effective on students’ actions regarding how much effort they expend on an activity and how long they put perseverance into an action when they face with difficulties. High efficacious students set challenging goals, put greater efforts on an activity, and persevere when dealing with difficulties. However, low efficacious students may not show perseverance and resilience when confronting setbacks (Pajares, 1996). In the literature, it has been reported that there was an increase in the number of students who lacked confidence and interest in science (Pell & Jarvis, 2001). Therefore, it is important to find ways to increase students’ self-efficacy. There is no study in the literature investigating the effect of metaconceptual teaching activities on students’ self-efficacy toward chemistry as a school subject. The purpose of this study was to examine the effectiveness of metaconceptual teaching interventions (MTI) on 10th grade students’ self-efficacy toward chemistry as a school subject compared to traditional instruction (TI). This study focuses on the following research question:

- What is the effect of MTI on 10th grade students’ self-efficacy toward chemistry when the effect of self-efficacy toward chemistry pretest scores is accounted for?

METHODS

Sample and population

The target population of this study was all 10th grade high school students in a city in Turkey. There are seven high schools in the city and all 10th grade students at seven of the two high schools were determined as the accessible population of the study. The sample of this study consisted of 102 students from two classes of each high school, which matched more than ten percent of the whole population. The sample of the study was chosen from the accessible population by using convenience sampling. There are three 10th grade science classes in each high school and two of the classes which were taught by the same chemistry teacher was randomly assigned to the experimental and control groups. Students’ socio-economic status was middle. The ages of the students are ranged from 15 to 16. Students in experimental groups were instructed by MTI and students in control groups were instructed by TI. There were 53 students (66% females and 34% males) in the experimental groups and 49 students (53% females and 47% males) in the control groups.

Instrument

To examine the effect of MTI on students’ self-efficacy toward chemistry, High School Chemistry Self-Efficacy Scale (HCSS) developed by Capa Aydin and Uzuntiryaki (2009) was administered to students. HCSS consisted of 16 items with a 9-point scale ranging from very poorly to very well in two dimensions: chemistry self-efficacy for cognitive skills (CSCS) and self-efficacy for chemistry laboratory (SCL). The CSCS was described as “students’ beliefs in their ability to use intellectual skills in chemistry” and the SCL was defined as “students’ beliefs in their ability to accomplish laboratory tasks including skills in both cognitive and psychomotor domain” (Capa Aydin & Uzuntiryaki, 2009, p. 872). The CSCS consisted of 10 items and the SCL consisted of 6 items. In a 9-point scale, very poorly was graded as 1 point and very well was graded as 9 point. Students needed up 10 to 15 minutes to complete the HCSS. The HCSS was piloted by the researcher with a sample of 330 high school students. It was found that HCSS consisted of the same two-factor structure as Capa Aydin and Uzuntiryaki (2009) proposed: CSCS (10 items) and SCL (six items). The internal consistencies of scores on the two dimensions were estimated by Cronbach alpha coefficient.

In the pilot study, Cronbach alpha reliability coefficients for the CSCS and SCL scores were found to be .86 and .93, respectively.

Procedure

In this study, the matching-only pretest-posttest control group design as a type of quasi-experimental design was used. Two months before the implementation started, the researcher was present at the research setting in order to have students get used to video recordings. During two months, the researcher recorded videos of the lessons of four classes included in the main study. The researcher also made observations during lessons in order to help her in selecting case studies for the main study in future. Furthermore, the researcher piloted metaconceptual activities prepared in chemical bonding topic during this time. The teachers in this study were trained for MTI during two months before the implementation began. To examine the effect of MTI on students' self-efficacy toward chemistry, HCSS was administered to the students in experimental and control groups two weeks before the treatment and at the end of the treatment. Before the study commenced, the researcher trained the teachers regarding MTI. Students in the experimental and control groups were taught by MTI and TI, respectively. There was a seven-week treatment period covering the science subject of "states of matter" with four-hour chemistry course a week. In the experimental group, several metaconceptual teaching activities such as poster drawing, journal writing, group discussion, and class discussion were included in order to facilitate students' metaconceptual processes. Metaconceptual teaching activities were arranged to make students aware of their own ideas, to monitor their understanding of a new concept, and to evaluate their ideas. The same set of activities such as experiments and class discussions was also used in the control group without explicit attempt to facilitate students' metaconceptual knowledge and processes. Table 1.1 shows a sample poster drawing activity used in the experimental group.

Table 1

A Sample Poster Drawing Activity

Aktivity: Poster Drawing

Types of metaconceptual processes that can be activated through poster drawing: Students' metaconceptual awareness, metaconceptual monitoring, and metaconceptual evaluation of their own ideas and ideas from other people/sources are tried to be activated.

Topic:

1. States of matter
2. Gas pressure
3. Pressure-temperature relationship in gases
4. Pressure-volume relationship in gases

Presentation of the topic:

1. Students will form five working groups of five students and the following questions were given as worksheets to the groups. Every student in the group will discuss her/his ideas on the answers of each question. Group discussions will be recorded on audiotapes.
   - How would you describe the difference among solids, liquids and gases?

Table 1 (*continued*)

- Suppose you had water in solid, liquid, and gas states. What do you think about the mass and density of water in each state?
- How can you draw the picture of solids, liquids and gases (for example, suppose you had water in solid, liquid, and gas states) in terms of the particulates that make up each?
- How can you explain gas pressure?
- What do you think how the gas pressure changes as altitude increases? Why?
- How can you explain pressure-temperature relationship in gases by giving daily life examples?
- How can you explain pressure-volume relationship in gases by giving daily life examples?

The groups will be given A3 papers and colorful pencils to draw their ideas on it. Every group will present their posters to the classroom.

Data analysis

Multivariate analysis of covariance (MANCOVA) was used to determine the effectiveness of two different instructional methods on students' self-efficacy toward chemistry by controlling the effect of students' CSCS and SCL pretest scores as covariates. MANCOVA has five assumptions: normality, homogeneity of regression, homogeneity of variance-covariance matrices, multicollinearity, and independency of observations. All these assumptions were checked and were satisfied.

RESULTS

The MANCOVA was conducted. Dependent variables of this study were post-CSCS and post-SCL scores and the fixed factor of this study was method of teaching. CSCS and SCL pretest scores were used as covariates. Before the study started, the necessary sample size for the desired power of the study was calculated. Cohen, Cohen, West and Aiken (2003) proposed effect size values for f^2 as "small" = .02, "medium" = .15, and "large" = .35. In this study, the effect size was set to a medium effect size measured by f^2 as .15 since there are not many studies to consider while deciding on the effect size. The significance level was set to .05 as in most of the educational studies. The power of the study was set to .80. The necessary sample size was calculated as 55. The results of the analysis revealed that there was a significant mean difference on the collective dependent variables of post-CSCS and post-SCL between experimental and control groups when the covariates were controlled (Wilks' λ = .93; $F(2,97) = 3.40$; $p = .04$). The partial eta square value was found to be .07 which indicated a medium effect size according to Cohen's (as cited in Pallant, 2001) suggestions (.01 = small effect, .06 = medium effect, and .14 = large effect). The power was obtained as .63 which was lower than the pre-calculated power value. In order to test the effect of the treatment on each dependent variable, an analysis of covariance (ANCOVA) was performed as follow-up tests to the MANCOVA. It was found that method of teaching had a significant effect on the dependent variable of post-SCL ($F(1,98) = 6.70$, $p = .01$) with medium effect size. Partial eta square was calculated as .07. The power of the study was found to be .73. However, method of teaching did not have a significant effect on the dependent variable of post-CSCS ($F(1,98) = 0.88$, $p = .35$).

CONCLUSIONS AND IMPLICATIONS

In the literature, there are studies modeling the relationship between motivational beliefs (including self-efficacy beliefs) and metacognitive strategy use (e.g., Sungur, 2007); however, there is no study investigating the effect of MTI on students' self-efficacy beliefs. For example, Sungur (2007) proposed a path model to examine the relationships among motivational beliefs, effort regulation in science courses, and metacognitive strategy use. She found that motivational beliefs and performance were predictors of students' metacognitive strategy use. The current study concluded that MTI increased students' scores on the collective dependent variables of post-CSCS and post-SCL and students' scores on the individual dependent variable of post-SCL compared to TI. Researchers have documented that modeling (Pajares, 1996) and feedback (Butler & Winne, 1995) increased students' self-efficacy. During the MTI treatment, students participated in the metaconceptual teaching activities such as poster drawing, group discussion, and class discussion and students' metaconceptual awareness, monitoring, and evaluation of their ideas were tried to be activated. Therefore, it could be said that throughout the MTI treatment, students found opportunities to get feedback on their ideas and to model their peers and teachers. Curriculum developers and teachers should be aware of the effect of MTI on students' self-efficacy and design the curriculum and courses accordingly. The further research could be conducted with large sample size to examine the effect of MTI on students' self-efficacy. Also, interviews could be conducted to get more detailed view for the effect of MTI on students' self-efficacy.

Differences in Students' Situational Interest and Learning Achievement Caused by Learning with Different Contexts

Eva Kölbach & Elke Sumfleth

Abstract: Although, context-orientation is implemented in the German school curricular of North Rhine-Westphalia (federal state of Germany), there is still a lack of research-based evaluation into the effects of their use. While most evaluation studies show that context-orientation has a positive influence on students' interest and motivation, context-effects on students' learning achievement are less positive and inconsistent (Bennett & Holman, 2002). Fechner (2009) showed for the chemistry domain that students learning with real-life contexts outperform students learning with subject-related contexts in a situational interest questionnaire as well as in accompanying achievement tests. However, effects vary depending on the implemented context.

The present study investigates context-effects on students' situational interest and learning achievement while learning different chemistry contents. Context-based worked-out examples served as learning material. Effects of the study were measured in a pre-post-follow-up design by the use of paper-pencil tests. Results show a main effect of context-oriented learning on students' situational interest with effects varying depending on the respective chemical content-knowledge.

Keywords: Context, Concept, Interest, Learning Achievement

1. INTRODUCTION

As a consequence of the weak performance of students in large scale assessments like *PISA* and *TIMSS*, the German government rethought about the German educational system. This move was underpinned by the implementation of federal state curricular determining that science concepts are better to be learned by students, when they are connected to real life problems. Therefore, in the new curricular of North Rhine-Westphalia every chemical concept is related to a (real-life) context, in which the concept has to be learned by the students. In this way context-orientation is used for pre structuring curricular content to help students to build a more in-depth understanding of scientific concepts. Furthermore, real-life contexts are supposed to increase students' interest in learning science as well as to show the relevance of science to them. In sum, the implementation of real-life contexts (in German science curricular) should (1) increase students' interest, (2) show the relevance of science to them and (3) enhance students learning achievement.

Research on context-oriented learning has shown positive effects of context-orientation on students' interest and motivation (Barber, 2000; Osborne & Collins, 2001; Ramsden, 1997; Yager & Weld, 1999). In comparison research on context-effects on students' learning achievement are inconsistent and less positive, so far (e. g. Barker & Millar, 2001; Gutwill-Wise, 2001).

Concerning the integration of situational interest and learning achievement Fechner (2009) showed for the chemistry domain that real-life contexts encourage students' interest in general. Thereby, an increase of interest, in turn, mediates an improved learning outcome. However, both effects varied depending on the implemented context.

In sum, research on context-oriented learning used a wide range of different context-based materials. Thus, drawing generalized predictions on the effects of context-oriented learning is difficult. Accordingly, Bennett and Holman (2002) showed that there is a comparative lack of systematic-based research into the effects of their use.
The present study contributes to a more detailed evaluation of context-effects of students' situational interest and achievement concerning two different chemistry concepts. Therefore, the following research question will be investigated: What influences do a real-life and a subject-specific context have on the learning outcome across two concepts within chemistry education? Therefore, it is suggested that students learning with real-life contexts outperform students learning with subject-related contexts regarding their situational interest as well as their acquired knowledge.

2. METHODS

To investigate the research question two contexts were chosen. The real-life one is *lakes* and the subject-related one is *school laboratory*. The first one is connected to students out of school experiences the latter one is close to students' everyday life experiences in classroom. In order to their prior knowledge students were assigned to one of these two context-groups. Each of the two context-groups was confronted with two topics taken from the chemistry curriculum, namely '*structure and solution of salt*' and '*structure of water-molecules*'. Each group were asked to learn with worked-out examples (according to Mackensen-Friedrichs, 2004) embedded in the respective contexts. Overall, eight worked-out examples were developed. Every example consists of a context-based problem statement (problem formulation), several problem solving steps (solution steps with reference to the respective context) and finally the solution itself (answer). While the context group learned with examples in which the respective chemistry concepts are embedded in the cover story *lakes*, the group without context learned the same concepts following the same solution steps embedded in a *laboratory environment* (see fig. 1).

Fig 1: Overview about the used design

To measure context-effects a pre-post-follow-up design was used. First of all, the assessed control variables were collected in the pre-test. Data from the pre-test were used to ensure, that context-effects will not be returned to differences in the treatment groups.

Afterwards, a two day long learning phase took place (fig. 1). During these intervention phases each context group was provided with worked-out examples, which are employed to learn the respective concepts embedded in one context. After each learning phase, a 20-minute paper-pencil test measuring situational interest and the learning achievement were administered to the students. The achievement test includes items measuring students' subject-specific knowledge as well as items measuring their ability to transfer knowledge. Four weeks after the intervention had taken place the achievement test was administered to the students again to measure their long term knowledge.

3. Results

The study was conducted with 176 9th graders from seven different higher track secondary schools in North Rhine-Westphalia. Students were excluded from the main analysis when (1) they were spotted as outliers in the data set (z-values > 3.29) or when they were missing at least one day. Therefore, the final sample consists of 158 students. The mean age of the sample was 14.5 years (SD = 0.6) and about 53% were female. In order to their prior knowledge, students were assigned to one of the two context-treatments. To check for group differences a Chi²-test (sex / treatment) as well as a multivariate analysis of variance [MANOVA] with interest, cognitive abilities (Heller & Perleth, 2000), prior knowledge and self-concept were calculated. Neither the Chi²-test ($\chi^2(1) = .65$; $p > .05$) nor the MANOVA ($F(9,143) < 1$) revealed a significant main effect of treatment, but there were marginal effects ($p < .10$) on two scales, which were treated as covariates in the following analysis.

First, a multivariate analysis of covariance [MANCOVA] with context (subject-related / real-life) showed a main effect of context on students' situational interest ($F(2,153) = 5.95$; p = .003, partial $\eta^2 = .072$). Students learning with real-life the context (M = 3.51; SD = 0.94) showed higher situational interest than students learning with the subject-related context (M = 3.06; SD = 0.92).

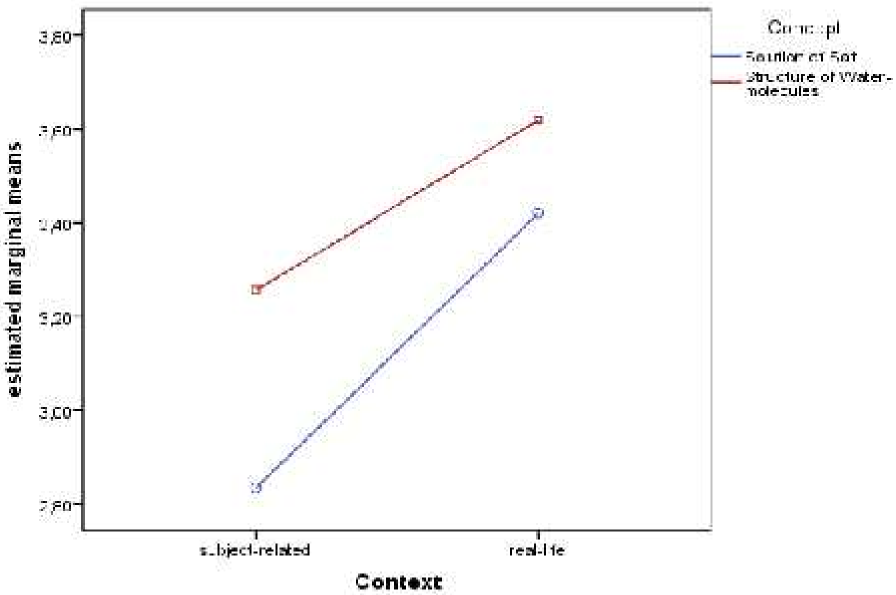

Fig2: Group differences in situational interest caused by context.

Thereby, effect-sizes varied depending on the respective content knowledge which should be acquired. Isolated analysis of covariance showed that effects were higher for the concept '*structure and solution of salt'* ($F(1,154) = 11.47$, p = .001; partial $\eta^2 = .069$) than for the concept '*structure of water-molecules*' ($F(1,154) = 5.37$, p = .022; partial $\eta^2 = .034$ (see fig 2). Therefore, it is suggested that water in this case is concept as well as context itself.

Second, data revealed an increased learning achievement from pre-test to post-test, $t(157) = 17.23$, $p < .001$, $d=1.3$. Therefore, it is suggested that the learning materials were conducive.

Third an analysis of covariance with context (subject-related / real-life) predicting students' learning achievement did not show any main effect of context ($F(2,153) = 1.64$; $p > .10$). Furthermore, data revealed no interaction effect of treatment and time of measurement (pre, post, follow-up). Also, none of the control variables served as moderator variable.

Fourth, an analysis of covariance with context (subject-related / real-life) predicting students' perceived relevance showed a main effect of context ($F(2,153) = 10.50$; $p < .001$, partial $\eta^2 = .121$). Students learning with real-life the context showed higher perceived relevance than students learning with the subject-related context. Thereby, effect-sizes varied depending on the respective content knowledge to be acquired. Isolated analysis of covariance showed that the effect was completely aroused by the concept '*structure and solution of salt'* ($F(1,154) = 19.56$, $p < .001$; partial $\eta^2 = .109$). There was no main effect of context for the concept '*structure of water-molecules*' ($F(1,154) < 1$ (see fig. 3).

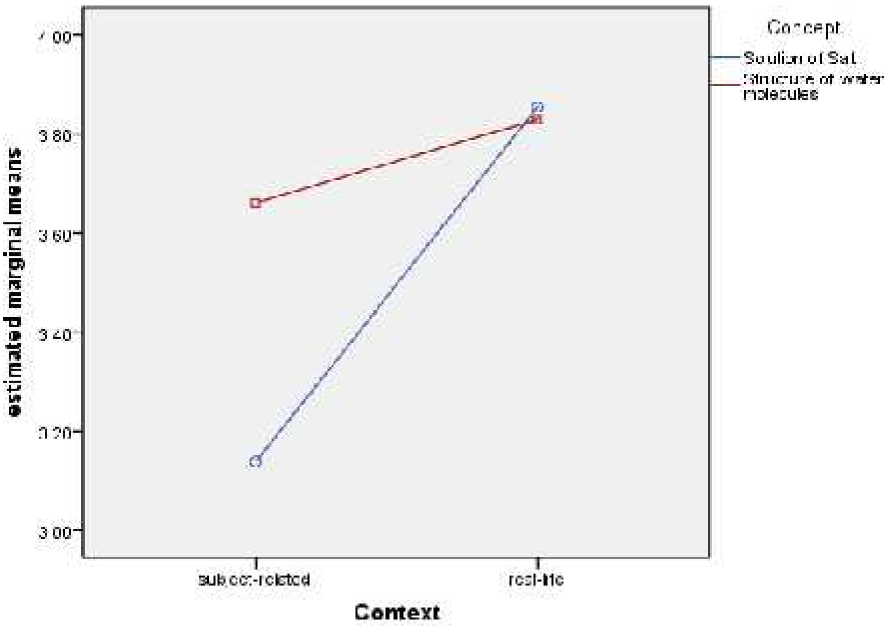

Fig. 3: Group differences in perceived relevance caused by context.

In sum, students learning with real-life contexts show – in line with our hypothesis – a higher situational interest than students learning with subject-related contexts. Contrary to our hypothesis there is no main effect of context on students' learning achievement. However, students' in the real-life context show an equal level of understanding of science concepts.

4. DISCUSSION AND CONCLUSIONS

Concerning educational implications, this research tries to provide evidence on how contexts can show the relevance of science to students' and increase students' interest in learning scientific concepts. Furthermore, it showed that the closer concepts and contexts are the smaller seamed the effect on students' situational interest and perceived relevance. In addition, it showed that in contrary to some criticism contexts don't hinder the development of scientific understanding.

HIGH SCHOOL STUDENTS' DOMAIN SPECIFIC EPISTEMOLOGICAL BELIEFS AND THEIR CONCEPTUAL CHANGE

Feral Ogan-Bekiroglu[1] and Ercan Kaymak[1]

[1]Marmara University

Abstract: Although research on epistemological beliefs has expanded and intensified considerably over the past two decades, there are still some issues that need to be explored. The purposes of this study were to determine high school students' epistemological beliefs in the domain of physics and to examine any relationship between their beliefs and their conceptual change in physics. Case study design with qualitative methods was guided to the research. The research was conducted with 17 tenth-grade students studying in an urban high school. Physics Related Epistemological Beliefs Instrument (PEBI) was developed to determine the students' epistemological beliefs in the domain of physics. Furthermore, Assessment Instrument for the Subjects of Work, Power, and Energy (AIWPE) was developed by considering the common misconceptions discovered in the literature review to assess students' conceptual change. Data were collected in the physics class and analyzed qualitatively. The following conclusions can be drawn from the study. First, high school students' level of epistemological beliefs in the domain of physics is very close to sophistication. Second, there is a positive association between the students' physics epistemological beliefs and their learning gains. This current study would contribute to the literature toward a better understanding of the relationship between beliefs and learning by using qualitative research methods.

Keywords: Epistemological beliefs, domain specific, conceptual change, high school students, physics

BACKGROUND AND PURPOSE OF THE STUDY

Research indicates that students' epistemological beliefs may either enhance or constrain the scope and nature of the motivational beliefs, learning strategies, and knowledge that are accessible to the learner as well as the nature and quality of various learning outcomes (Paulsen & Wells, 1998). Therefore, students' epistemological beliefs have come into prominence. Although there is valuable research on epistemological beliefs, there are still some issues that need to be explored. One issue that is under discussion is how epistemological beliefs are related to learning. The purposes of this study were to determine high school students' epistemological beliefs in the domain of physics and to examine any relationship between their beliefs and their conceptual learning in physics.

THEORETICAL FRAMEWORK

Theoretical framework of this study is based on the conceptual change model (or CCM) developed by Posner, Strike, Hewson, and Gertzog (1982). According to this model, learning involves an interaction between new and existing conceptions with the outcome being dependent on the nature of the interaction. There are two major components to the CCM (Hewson, 1992). The first of these components is the conditions that need to be met (or no longer met) with the status of a person's conception in order for a person to experience conceptual change. The second component is the person's conceptual ecology (following Toulmin, 1972) described as the existing interrelated networks of concepts that influence the selection of a new concept playing a central and organizing role in thought. Several elements of conceptual ecology are identified as anomalies, analogies, metaphors, epistemological beliefs, metaphysical beliefs, knowledge from other areas of inquiry, and knowledge of competing conceptions. Therefore, personal epistemological beliefs, namely, beliefs about the nature of knowledge and acquisition of knowledge were considered as playing an important role in learning.

LITERATURE REVIEW

A few researchers have investigated student epistemologies in the domain of physics. May and Etkina (2002), for instance, illustrated that students with high conceptual gains tended to show reflection on learning that was more articulate and epistemologically sophisticated than students with lower conceptual gains. Moreover, Songer and Linn (1991), Qian and Alverman (1995), and Stathopoulou and Vosniadou (2007) put forward some evidence presenting the relationship between constructivist physics epistemology and conceptual understanding. Qian and Alvermann (1995) carried out canonical correlation analyses and expressed that beliefs about simple-certain knowledge contribute the most to conceptual change learning, whereas beliefs about innate ability contribute the least. Naive epistemological beliefs have long been identified as a major impediment to the achievement of conceptual change in science education (Thoermer & Sodian, 2002).

Moreover, (Hammer, 1994) studied college students' beliefs about the structure, content, and learning processes of physics and Roth and Roychoudhury (1994) examined the constructivist or objectivist ''epistemological commitment'' of high school physics students. Results of this study would add to the literature by exploring interrelationship between individuals' physics epistemological beliefs and their conceptual change.

METHODS

Case study design (Stake, 1995) with qualitative and quantitative methods was guided the research.

Participants and Setting

The research was conducted with 17 tenth-grade students studying in an urban high school. Their average age was 16. There were 9 females. Data were collected in their physics class.

Measurements

Two instruments were developed and used for this study. Physics Related Epistemological Beliefs Instrument (PEBI) was developed to determine the students' epistemological beliefs in the domain of physics. Schommer (1990) proposed four dimensions to measure epistemological beliefs. These dimensions are simple knowledge and certain knowledge- naive beliefs about the nature of knowledge- and innate ability and quick learning- naive beliefs about the acquisition of knowledge. Her dimensions were taken into account for this research. Thus, eight open-ended questions based on the dimensions were created for the PEBI. The questions were prepared to ask students their opinions about some scientific claims and whom they agree with in controversial dialogues between two people. Furthermore, Assessment Instrument for the Subjects of Work, Power, and Energy (AIWPE) was developed to assess students' conceptual change. The AIWPE consisted of 13 open-ended questions measuring conceptual and procedural knowledge. Each question is worth five points; thus, the highest score that someone gets from the instrument was 65. Based on Bloom's Taxonomy, one question was in knowledge level, four questions were in comprehension level, three questions were in application level and five questions were in analysis level.

Content and face validities of the instruments were ensured by working together with three experts. They were both pilot tested.

Data Collection

The PEBI was used in the semi-structured interview protocol. The interviews lasted 20 to 45 minutes and were video-recorded. Video records were examined to make sure that the interviewer did not orient students without being aware of. The students' knowledge of work, power and energy subjects was assessed in the pre-test before the instruction started. The instruction lasted six weeks. They gave their responses to the questions in the AIWPE one more time in the post-test. Each application lasted one lesson hour.

Data Analysis

Data were analyzed qualitatively. The students' epistemological beliefs were categorized as low, medium, high, and very high for each dimension because beliefs are held in clusters. The students' knowledge for each question was categorized as compatible elaborate, compatible sketchy, compatible-incompatible, incompatible sketchy, incompatible elaborate, and no response based on the bidemensional coding offered by Hogan and Fisherkeller (1996). Based on this scale, participants' response concurring with the scientific proposition and having sufficient detail to show the thinking behind them was coded as "compatible elaborate". However, if the essential details were missing, it was coded as "compatible sketchy". Participants' response disagreeing with the scientific proposition and having details or coherent logic was coded as "incompatible elaborate". Nevertheless, if very little detail or logic was given in the response, it was coded as "incompatible sketchy". If the participant made sketchy statements concurring with the scientific proposition and s/he also made sketchy statements disagreeing with the scientific proposition, his/her knowledge was coded as "compatible/incompatible". If there was no response, it was coded as "no response".

In order to determine if the change between pre- and post-tests was significant, paired samples t-test was performed.

One of the authors categorized all of the participants' beliefs. The other author also categorized some randomly selected students' beliefs. Then, two authors compared their categorization and reached 87% of agreement. They re-categorized the beliefs that they could not have agreement on and gave final decisions together. Interrater reliability value for the knowledge categorization was 91%. The authors worked on the categories where there was disagreement and reached consensus.

After coding process was completed, the researchers looked for patterns (Miles & Huberman, 1994) among the students' epistemological beliefs, conceptual change and learning strategies to find a relationship and to explain this relationship.

RESULTS AND DISCUSSION

The students' epistemological beliefs in the domain of physics are shown as percentage values in Table 1.

Regarding simplicity of knowledge dimension, more than a half of the students' (59%) were able to reach high level, 29% of the students had medium level beliefs, and 12% of them held low-level beliefs. In certainty of knowledge dimension, on the other hand, 6% of the students had very high-level beliefs, 59% of them had high-level beliefs, and 35% of them held medium-level beliefs. In innate ability dimension, 6% of the students had very-high level beliefs, 70% of them had high-level beliefs, 18% of them held medium-level beliefs, and 6% of them held low-level beliefs. In terms of quick learning dimension, while high population of the students (88%) had high-level beliefs, 6% of the students achieved to very high levels, and only 6% of them held medium-level beliefs. Findings show that majority of the students' epistemological belief level in the domain of physics was high. This result is compatible with Yang's (2005) finding that most students were multiplist. On the other hand, the result of the current study is not in line with May and Etkina (2002)'s result. They demonstrated that many high school students considered science as a collection of facts and did not differentiate between observational evidence and explanations of this evidence. Findings of the current study also reveal that the dimension that nearly all of the students developed nearly sophisticated physics epistemological beliefs in was quick learning dimension. That is, the students believed that learning was a gradual enterprise and did not occur quickly. However, it was hard for almost a half of the students to believe that knowledge was composed of highly interrelated concepts.

Table 1. *Percentage values of the students' epistemological beliefs in the domain of physics (N=17)*

Dimensions	**Epistemological Beliefs in the Domain of Physics (%)**			
	Low	**Medium**	**High**	**Very High**
Simplicity of Knowledge	12	29	59	0
Certainty of Knowledge	0	35	59	6
Innate Ability	6	18	70	6
Quick Learning	0	6	88	6

The results of paired samples t-tests illustrated that the students showed significantly higher performance in the post-test than they showed in the pre-test ($M_{Pre–Post}$ = -1.08), t (16) = -7.69, $p < 0.001$. There was no correlation between two tests (r = 0.12, p = 0.648). That is, it is not possible to say that the students whose scores were high in the pre-test had high scores in the post-test.

Each student's physics epistemological beliefs in four dimensions and their knowledge level before and after the instruction are shown in Table 2. While, 65% of the students raised their learning to compatible sketchy level after the instruction, 18% of them were able to reached compatible elaborate level. Although 12% of the students (Student 10 and Student 14) kept their compatible / incompatible knowledge level in the post-test, there was an increase in their scores. On the other hand, Student 11 (5%) did not change his knowledge level and decreased his post-test score by two points. However, his knowledge level had already been high and concurred to compatible sketch level. These findings illustrate that conceptual change process occurred and almost all of the students somehow repaired their misconceptions.

Findings with regards to the students' high level epistemological beliefs in the domain of physics and their knowledge gain direct us to the positive relationship between domain-specific epistemological beliefs and learning within the same domain. Mason (2002) explains this relationship as follows: Students having sophisticated beliefs about the nature and acquisition of knowledge can develop and refine thinking dispositions crucial to fostering learning through knowledge revision. Results of this study are consistent with the results of other studies (May & Etkina, 2002; Songer & Linn, 1991; Stathopoulou & Vosniadou, 2007).

Most of the students' physics epistemological beliefs in the dimension of quick learning were close to the advanced level. Likewise, most of the students increased their learning after the instruction. On the other hand, none of the students' physics epistemological beliefs in the dimension of simplicity of knowledge were in advanced level. Furthermore, two of the students had unsophisticated beliefs in this dimension. Similarly, most of the students could not improve their knowledge to the highest level i.e. compatible elaborate level in the questions required them to do analysis. Consequently, students' physics related epistemological beliefs in the dimensions of quick learning and simplicity of knowledge may be good predictors in their conceptual change process in physics. Students with beliefs in gradual learning may study more to reach their learning goals. Students who view physics knowledge as a complex system of organized and re-organized theoretical concepts may think critically and consider alternative views (Stathopoulou & Vosniadou, 2007). Thus, students having sophisticated beliefs in the dimensions of quick learning and simplicity of knowledge are likely to be successful in knowledge acquisition. Qian and Alvermann (1995) found the parallel result regarding general epistemological beliefs.

CONCLUSIONS AND IMPLICATION

The following conclusions can be drawn from the study. First, high school students' level of epistemological beliefs in the domain of physics is very close to sophistication. Second, there is a positive association between the students' physics epistemological beliefs and their learning gains. Third, sophisticated domain-specific epistemological beliefs especially in the dimensions of simplicity of knowledge and quick learning are prerequisite for conceptual change.

This current study would contribute to the literature toward a better understanding of the relationship between beliefs and learning by using qualitative research methods.

ITS CHEMISTRY! AN INTERVENTION PROGRAMME AIMED AT DEVELOPING THINKING SKILLS IN CHEMISTRY

Maria Sheehan[1] and Peter E. Childs[2]
[1]St. Caimin's Community School, Shannon, Ireland
[2]Department of Chemical and Environmental Sciences, University of Limerick, Limerick, Ireland

Abstract: '*ITS Chemistry'* is an intervention programme aimed at developing the thinking skills of Irish second level Chemistry pupils. It also aims to address the chemical misconceptions pupils possess about fundamental Chemistry topics, while also attempting to make abstract topics, such as the Particulate Nature of Matter (PNM) and the Mole, more concrete and tangible for the learner. This programme infuses strategies and methodologies, which have been shown in Chemistry Education Research to be successful in developing thinking skills and understanding, into the established Leaving Certificate Chemistry syllabus. This paper outlines the development, implementation and evaluation of the *'ITS Chemistry'* intervention programme. Results indicate that this programme produced positive effects both on the pupils' cognitive development and also on their performance in a chemical misconceptions test.

Keywords: second level chemical education, chemical misconceptions, particulate nature of matter, the mole concept, cognitive development.

BACKGROUND

This paper reports the results of phase 3 of a project looking at the difficulties in the learning of Chemistry in the Irish school system. In phase 1 the main problem areas/topics in Chemistry were determined for Irish second-level Chemistry pupils and university level students. (Childs and Sheehan, 2009b). Phase 2 investigated the cognitive levels that pupils/students were operating at and the numbers and types of chemical misconceptions they possessed about fundamental topics in Chemistry (Sheehan and Childs, 2011).

Chemistry is known to be one of the most difficult and conceptually challenging subjects on the school curriculum. Many factors contribute to its difficulty and much work has been carried out in attempting to make the content of this subject more accessible. Chemistry by its nature is abstract and requires formal operational thought and contains many higher order chemical and mathematical concepts; thus anyone not operating at this level of cognitive development will have difficulty with Chemistry. Chiappetta (1976) concluded after studying a number of investigations '*that most adolescents and young adults have not attained the formal operational stage of cognitive development*'. In Ireland, it has been found that approximately 8.7% of Junior Certificate pupils (~16 years of age) and 17.7% of Leaving Certificate (LC) Chemistry pupils (~18 years of age) have reached the formal operational stage (Childs and Sheehan, 2009a). The fact that the majority of Irish pupils studying Chemistry at school are still operating at the concrete level may explain the difficulties many pupils have with Chemistry.

Chemical misconceptions are another reason why pupils find particular topics in Chemistry difficult. The chemical misconceptions pupils have will have a major effect on the learning and understanding of advanced topics in Chemistry. Ausubel (1978) stated that if he '*had to reduce all of educational psychology to just one principle, he would say this: the most important single factor influencing learning is what the learner already knows. Ascertain this and teach accordingly'.*

Results of misconceptions tests carried out on Irish Junior and Leaving Certificate Chemistry pupils indicate that they possess a large number of misconceptions relating to PNM and the Mole. (Sheehan and Childs, 2011)

RATIONALE FOR THE DEVELOPMENT OF THIS INTERVENTION PROGRAMME

Many intervention programmes have been developed which have aimed to enhance pupils' thinking skills; these include: the Instrumental Enrichment Approach (I.E), Philosophy for Children (P4C), Cognitive Acceleration (CA) and the Infusion Approach. The Cognitive Acceleration through Science Education (CASE) programme has been credited with producing large cognitive development gains for participants. The CASE programme materials, *'Thinking Science',* introduced and developed formal operational thinking patterns over two years with a large cohort of UK children (Dickson, T., 2004). There are problems introducing this into the Irish classroom and consequently our programme was developed using an infusion approach, working within the constraints of the Irish Chemistry syllabus. '*ITS Chemistry*' stands for 'Increasing Thinking Skills in Chemistry'. It was influenced by successful strategies and methodologies used in developing the thinking skills of pupils but infused these into the current LC Chemistry syllabus; it also addresses chemical misconceptions and tries to alleviate difficulties pupils are having with Chemistry, while still achieving the syllabus aims and objectives.

METHODOLGY

Prior to the development of the resource package used in this intervention programme, a number of tasks had to be carried out:

1. A Cognitive Analysis Taxonomy (CAT) was carried out on the topics to be included in the intervention programme in order to develop a logical progression through the lessons.
2. A list of chemical misconceptions, relating to the topics included in the intervention programme, was constructed in order to alert teachers to their presence.
3. The LC Chemistry syllabus was analysed to ensure the intervention programme was covering the syllabus.

This intervention programme was developed for pupils who had just completed their JC Science examination and who had chosen to study LC Chemistry. The intervention covered the initial 12 weeks of the course and was based on the following research findings:

- Results of phase 1 showed that pupils were having difficulty with abstract Chemistry topics that would require formal operational thinking;
- Results from phase 2 of the showed that the majority of Irish JC Science and LC Chemistry were operating at the concrete operational stage, making it difficult for them to tackle abstract topics;
- Results of phase 2 also indicated that JC and LC pupils possess a large number of chemical misconceptions about fundamental Chemistry topics.

The topics chosen to be covered as part of the intervention programme were the Particulate Nature of Matter (PNM) and the Mole Concept for the following reasons:

- Previous investigations (Childs and Sheehan, 2009b) have shown that the Mole and calculations involving the Mole are perceived by pupils as being difficult;
- The Particulate Nature of Matter was identified as an topic in which pupils possessed many misconceptions;
- These topics have been described as threshold topics (Meyer and Land, 2003), which are important if a pupil is to understand more difficult Chemistry topics later in the course;
- These topics are covered at the start of the LC Chemistry course.

Figure 1 outlines the content of the 12 week *'ITS Chemistry'* programme.

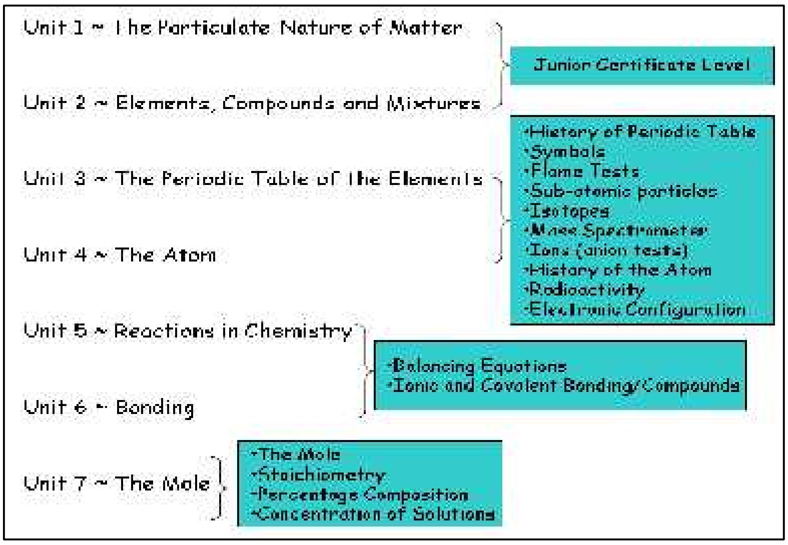

Figure 1: Structure and content of the 'ITS Chemistry' intervention programme

Figure 2 outlines the different areas of Chemistry Education Research that inspired and shaped this intervention programme.

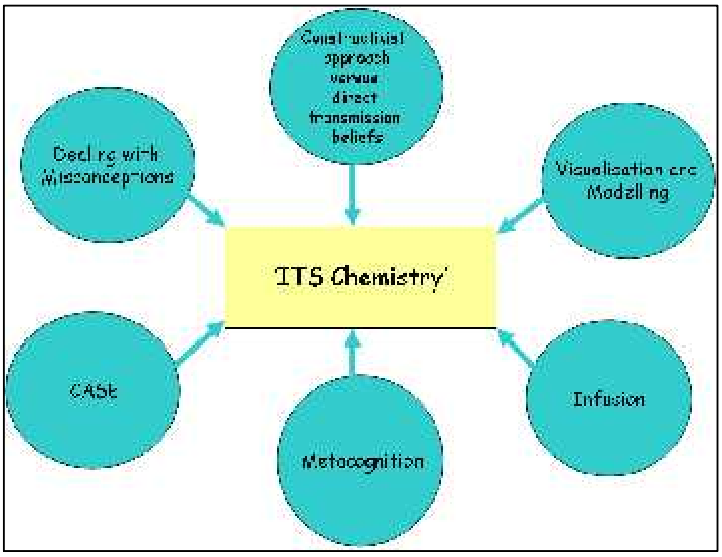

Figure 2: Areas of educational research that inspired the development of 'ITS Chemistry'

Successful strategies were identified from the different areas listed in Figure 2 and were infused into the current LC Chemistry syllabus for the Particulate Nature of Matter and the Mole concept. Using the infusion approach means there is not only an enrichment in content and learning experiences, but also there is no loss of time in covering the syllabus, making it attractive to the teachers.

The *'ITS Chemistry'* intervention programme paid particular attention to the introduction of topics through concrete exercises, along with cognitive conflict and the social interaction aspects of the CASE lessons. These approaches not only promote the development of cognitive ability, but they effective in addressing and reduce pupils' chemical misconceptions. The structure and key design features of a typical '*ITS Chemistry'* lesson are shown in Figure 3.

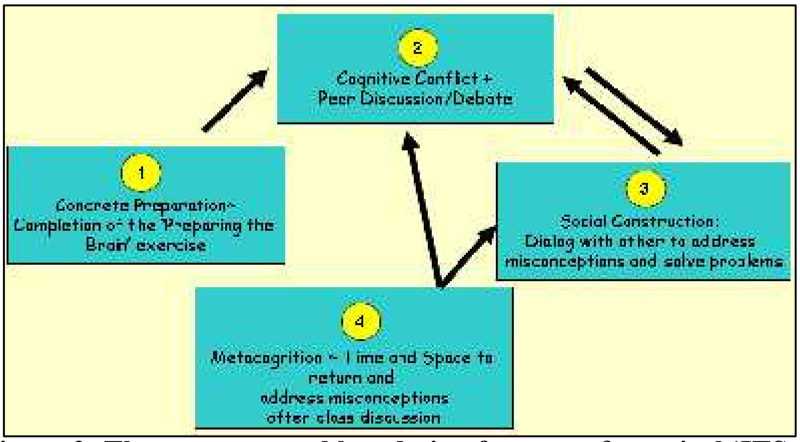

Figure 3: The structure and key design features of a typical 'ITS Chemistry' lesson

Each '*ITS Chemistry'* lesson began with a revision of previous ideas and with an explanation of terms and description of equipment that the pupils would be using during the lesson, and this section in the pupils' handbook was titled *'preparing the brain'* and focused pupils on what coming next. Figure 4 illustrates an example of a *'preparing the brain'* activity.

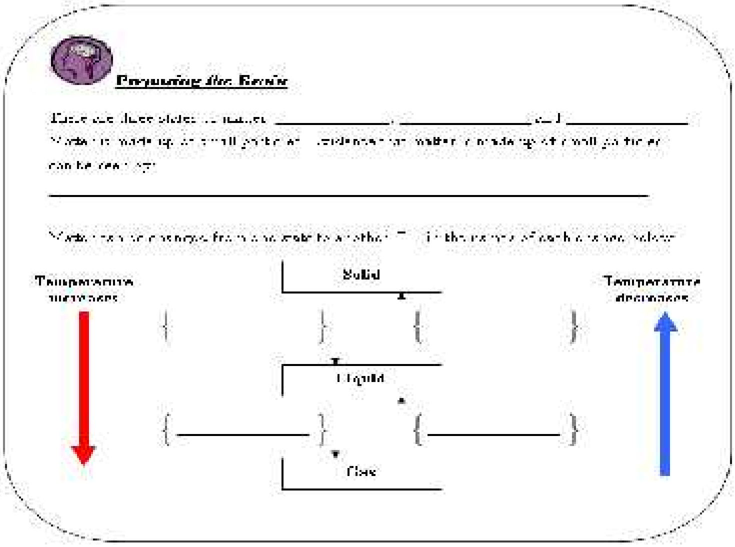

Figure 4: Example of a 'preparing the brain' activity which appeared at the beginning of each of the ITS Chemistry lessons

Lessons also included practical, hands-on activities and tasks focused around social interaction between pupils. They were used to provide pupils with an opportunity to discuss what was happening and why. Cognitive conflict was initiated as a result of social interaction and teacher intervention and was done through group and teacher-led discussion. Discussion of ideas and concepts also play an important role in the identification and altering of chemical misconceptions. While many philosophies of thinking influenced the *ITS Chemistry* programme, it is in fact an infusion approach aiming to develop thinking skills both *within* and *through* the course content. Metacognition was encouraged in this intervention programme by allocating time in the lesson and space in the Pupils' Workbook to return and correct answers to questions. In the homework exercises pupils completed activities relating to those studied in class and were encouraged to explain their answers.

The teachers taking part in the implementation of this programme received training at the start of the school term, and the theoretical background covered was also included in the Teacher's Handbook. The cognitive development of pupils was assessed at the start of the programme using Science Reasoning Task Three. After completing the 12 week programme they completed a post-

test: this took the form of another Science Reasoning Task and also a chemical misconceptions test; these reasoning scores were compared with the pre-test scores. Cognitive development and the types and numbers of misconceptions of the experimental group were compared with a control group, who covered the same material in the traditional way. The teachers' views were collected through a teacher's diary and a short questionnaire at the end of the project.
The research questions to be answered by this investigation are as follows:

1. Can cognitive acceleration be achieved through infusing a cognitive acceleration technique into the normal Irish Chemistry syllabus?
2. Can chemical misconceptions be addressed at the start of the LC Chemistry course and thus alleviate difficulties pupils have with crucial Chemistry topics?
3. Does this research-based teaching strategy increase pupils' understanding of the Particulate Nature of Matter and the Mole?

Table 1: Profile of the experimental group that participated in phase 3 of this investigation

	Profile of Experimental group for phase three of this investigation (n= 93)
Age Profile	15 Years Old = 24.7% 16 Tears Old = 71.0% 17 Years Old = 2.2% Missing = 2.2%
Gender Profile	Male = 42 (45.2%) Female = 51(54.8%)
Breakdown of pupils' Mathematics level for the Junior Certificate Examination	Higher Level = 54 (58.1%) Ordinary Level = 37 (39.8%)
Breakdown of pupils' Science level for the Junior Certificate Examination	Higher Level = 77 (82.8%) Ordinary Level = 14 (15.1%)

In total 5 schools (6 different class groups, 93 pupils) trialled the '*ITS Chemistry'* intervention programme., one of which was the school of one of the researchers (MS). The profile of the experimental group involved in the implementation of the ITS Chemistry programme is given in Table 1.

Table 2: Profile of the control group that participated in phase 3 of this investigation

	Profile of the control group for phase three of this investigation (n= 57)
Age Profile	15 Years Old = 17.5% 16 Tears Old = 50.9% 17 Years Old = 26.3% Missing = 5.3%
Gender Profile	Male = 38 (66.7%) Female = 19 (33.3%)
Breakdown of pupils' Mathematics level for the Junior Certificate Examination	Higher Level = 41 (71.9%) Ordinary Level = 13 (22.8%)
Breakdown of pupils' Science level for the Junior Certificate Examination	Higher Level = 54 (94.7%) Ordinary Level = 3 (5.3%)

Table 2 shows the profile of the control group (4 schools, 57 pupils) used in this investigation. It is important to note that a higher percentage of the control group took the more difficult higher level examination in Science for the Junior Certificate than the experimental group. This may indicate that the control group are initially stronger in Science than the experimental group.

RESULTS AND CONCLUSIONS

Results from this intervention programme indicate a positive effect of participation in the '*ITS Chemistry'* programme on their performance in a chemical misconceptions test. Figure 5 shows the experimental group's performance compared to the control group. Both groups had covered the same Chemistry content.

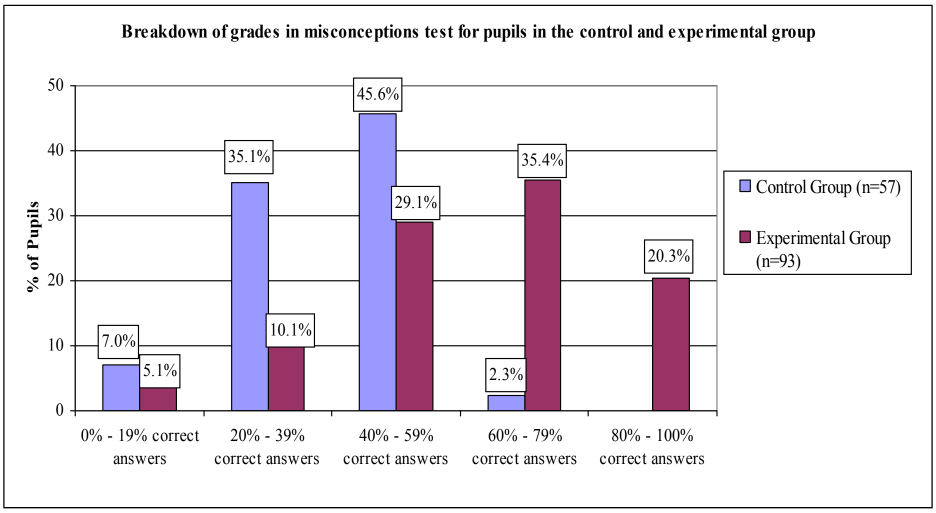

Figure 5: Comparison of results for the chemical misconceptions test for the control and experimental group

The results show that the experimental group performed better in the chemical misconceptions test than the control group. This is an encouraging finding, considering that pupils in the control group were stronger at Science initially than those in the experimental group. Overall 42.1% of the control group scored less than 40% in the chemical misconceptions test, compared to 15.2% of pupils from the experimental group; 20.3% of the pupils in the experimental group achieved more than 80% in the test; whereas no pupil from the control group scored above 80%.

The intervention programme also had a positive effect on the cognitive level of the experimental group. Figure 6 shows the summary of the changes in cognitive levels after participation in the intervention programme for the experimental group.

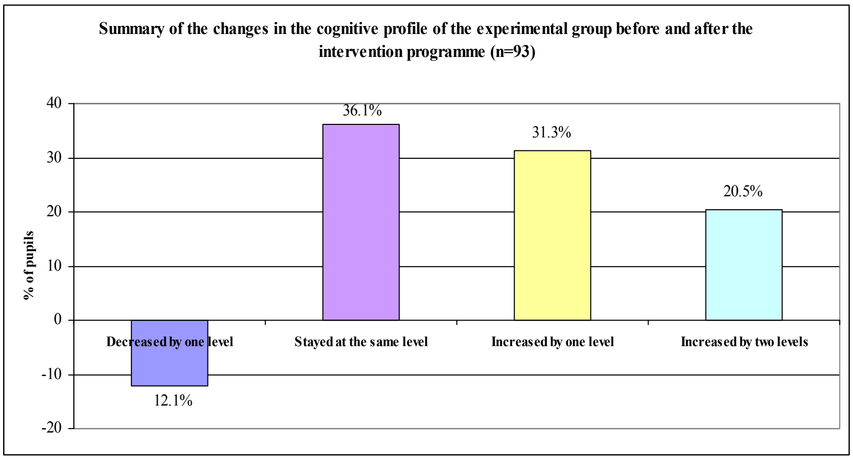

Figure 6: Summary of the changes in cognitive levels after participation in the intervention programme

The results indicate positive effects on the pupils' cognitive development after participation in the '*ITS Chemistry'* intervention programme: 51.8% increased their cognitive level.

The initial results from this intervention programme indicate that it is indeed possible to improve the thinking skills of pupils, through an infusion of different teaching methodologies into the Irish LC Chemistry syllabus. This short intervention (12 weeks) increased the percentage of pupils operating at the formal level of cognitive development compared to their initial level, and the percentage of the experimental group operating this level significantly exceeded that of control group and the LC cohort previously studied, indicating the potential of this approach to raise cognitive levels. There is no doubt that *'ITS Chemistry'* has also been successful in addressing the chemical misconceptions possessed by pupils.

This intervention project has shown that it is possible to develop lessons to include research-based methodologies without interfering with the delivery of the prescribed syllabus. The approach taken in this intervention programme should be applied to the whole LC Chemistry syllabus, and this might help to alleviate the difficulties pupils currently have with many Chemistry topics. The positive effects shown on both the cognitive ability and reduction of chemical misconceptions in this short intervention project suggest that using this approach for the whole course would have very significant results.

Since the research was completed (in May 2010) the authors have had the opportunity to disseminate the ideas and materials to teachers in several workshops. The ideas and teaching materials have been well received and it is intended to continue to disseminate the materials and encourage their use. It is also intended to compare the examination results in Chemistry for the experimental and control groups at the end of their LC course (in June 2011), in order to see if the intervention programme had a long-term effect on pupils' performance.

We believe that 'ITS Chemistry' has demonstrated the value of using the findings of Chemistry Education Research to change the way Chemistry is taught in schools, in order to produce more effective learning and deeper understanding of the subject.

INVOLVING STUDENTS IN RESEARCH ON THE USE AND CONSTRUCTION OF CONCEPT CARTOONS FOR CHEMISTRY CLASSES

Rosina Steininger[1] *and Anja Lembens*[1]
[1] Austrian Educational Competence Centre Chemistry, University of Vienna

Abstract: A student-scientist partnership is presented where students and their teachers are involved in science educational research on the use and conceptual design of Concept Cartoons. The purpose of the ongoing collaborative research is twofold: First, the use of Concept Cartoons in chemistry education shall be investigated and improved. Second, the students get the opportunity to engage in authentic research, and the learning outcome associated with the research apprenticeship is explored.

At the participating schools students were trained to interview younger students in order to identify their pre-conceptions. Using these beliefs, they have created Concept Cartoons that will be used and evaluated in class in the course of the second year of the project.

The paper focuses on the participant perceptions of the student-scientist partnership. The data source consists mainly of the students' self-reports. Preliminary results suggest that the students have benefitted from their involvement in the research project in terms of scientific content knowledge, skills, confidence and self-efficacy, intellectual development, satisfaction and discourse practices.

*Keywords***:** research apprenticeship, student-scientist partnership, Concept Cartoons, learning outcome

INTRODUCTION

Student research apprenticeships offering learners opportunities to engage in authentic scientific inquiry have become increasingly popular over the past few decades. At secondary level these apprenticeships are organized either as extra-curricular programs or as classroom-based student-scientist partnerships (SSP). Much research has been done on the learning outcomes associated with participation in research apprenticeships (Sadler, Burgin, McKinney & Ponjuan, 2010). The Austrian Federal Ministry for Science and Research runs a program called "**Sparkling Science**"[1], in which scientists are asked to do research in collaboration with students and teachers. The intention is to break down structural barriers between school and university for the benefit of both.

The research project presented in this paper is supported by "Sparkling Science". Its objectives are to investigate and improve the use of Concept Cartoons in chemistry education together with upper secondary students and their teachers. At the same time we want to explore the students´ benefits from the collaborative research project. Different to most SSP-projects, where the researchers are chemists, biologists etc., in this case the researchers

[1] http://www.sparklingscience.at/en/

involved are educational researchers. In this paper we concentrate on the benefits students gain through this partnership.

Based on constructivism, Concept Cartoons were first developed in the 1990s by Keogh and Naylor (1999). They were primarily intended as a teaching and learning aid and are frequently used as a surveying method to identify learners´ alternative conceptions. The cartoons show students in everyday situations discussing a scientific topic. Both scientifically acceptable viewpoints and alternative conceptions are shown in speech balloons. The students are asked to comment on these statements, and to use their existing knowledge to describe their own assumptions regarding the main question of the cartoon. Contrary to a multiple-choice test item, the task is not to find “the right answer” in one of the speech balloons but to question ways of thinking and to argue about the ideas. Thus students’ conceptions will become visible and debatable, and first steps towards conceptual growth or change can be taken (Stenzel & Eilks, 2005; Treagust & Duit, 2008). Furthermore, Concept Cartoons can be used to promote students’ argumentation in science (Chin & Teou, 2009; De Lange, 2009). Teaching and learning argumentation in a scientific context facilitates lifelong learning of science-related issues as well as participation in social issues (Osborne, Erduran, & Simon, 2004). In addition, we assume that using Concept Cartoons is a promising tool to initiate comprehensible learning (Lembens & Steininger, 2011).

The project involving three secondary schools in Vienna and Graz (Austria) started in September 2010 and will end in August 2012. At the beginning, the secondary school teachers used Concept Cartoons specially designed for their needs in accordance with the curriculum. After becoming acquainted with Concept Cartoons upper secondary school students were introduced to learning theories, constructivism and the importance of students´ conceptions for successful and sustainable learning. Additionally, they received training in interview techniques and learned how to design Concept Cartoons. Equipped with these competencies they interviewed lower secondary school students in order to find out their conceptions of selected topics concerning acids and bases. After analyzing and interpreting the interview records in collaboration with the educational researchers, the upper secondary school students designed Concept Cartoons incorporating the interviewees’ beliefs. In an iterative process these Concept Cartoons will be used and tested by the teachers in a lower secondary class, while the upper secondary school students will support the younger students during their group discussions focussing on the topic presented by the newly designed Concept Cartoons.

AIM/RESEARCH QUESTION

In general, a student-scientist partnership is a collaboration between a scientist or group of scientists, the students of one or more classes and their teacher(s) who all work together on a topic or question commonly originating from the scientists´ recent field of research. The students´ learning outcome and the quality of their involvement are of interest for science educational researchers, who look at this from outside as they are not part of the authentic scientific inquiry the student-scientist partnership is about.

In this project the structure is slightly different. Students themselves are involved in science educational research. The object of research is the use and construction of Concept Cartoons for chemistry classes. The science education researchers are at the same time both part of the student-scientist partnerships and evaluating the students´ benefit.

In this paper we deal with the following research question: How do the students benefit from the collaborative research project "Comprehensive Learning through Concept Cartoons"? To subdivide this general question into different aspects we use categories presented by Sadler et al. (2010), such as scientific content knowledge, skills, confidence and self-efficacy, intellectual development, satisfaction and discourse practices.

METHODS

To assess the learning outcome initiated through the involvement in the research project on Concept Cartoons, both quantitative and mainly qualitative research instruments have been applied.

At the beginning the upper secondary school students filled in a questionnaire (five-level Likert-type scale) on their chemical self-concept and their motivation in learning chemistry. For both, existing instruments were adapted (Dickhäuser, Schöne, Spinath & Stiensmeier-Pelster, 2002; Müller, Hanfstingl & Andreitz, 2007).

At the same time teachers completed an open-ended questionnaire on their expectations of the collaborative project and their experience in dealing with students' conceptions and argumentation in science classes. Following the approach of participatory action research (Altrichter & Posch, 2007), the teachers were asked to document their experiences by keeping a research diary.

At each school 2- to 4-hour-long "project lessons" were audio- and videotaped three to five times, additional field notes were taken as well.

At the end of the first year of collaboration the students were asked to write reflective papers documenting their experiences made so far, and semi-structured interviews were conducted with the three teachers.

All qualitative data has been and will be evaluated using content analysis following Mayring (2007).

RESULTS

As the project is still on-going, the presented results are preliminary.

Quantitative Data

The statistical evaluation of the students´ questionnaires shows that the classes at school 1 and school 3 are quite similar in terms of motivation in learning chemistry. Students at school 2 achieve lower results. A value of -12 indicates exclusively extrinsic motivation whereas +12 means entirely intrinsic motivation.

Descriptive statistics of students´ motivation measured as self-determination index (SDI)						
School No.	**sex**	**N**	**min**	**max**	**M**	**SD**

school 1	girls	12	-5.35	4.20	**0.98**	3.00
	boys	11	-0.65	10.60	**3.58**	3.73
school 2	girls	10	-2.80	8.25	**1.51**	3.88
	boys	5	-3.75	4.95	**-1.28**	3.63
school 3	girls	8	-4.70	5.70	**0.66**	3.87
	boys	19	-4.00	11.10	**3.06**	4.04

Table 1: Descriptive statistics of students´ motivation measured as self-determination index (SDI)

At schools 1 and 3 the boys seem to be more intrinsically motivated than the girls whereas at school 2 the situation is quite the opposite.

Descriptive statistics of students´ chemistry self-concept						
School No.	**sex**	**N**	**min**	**max**	**M**	**SD**
school 1	girls	13	10	19	**14.15**	3.18
	boys	14	7	25	**17.29**	4.80
school 2	girls	10	11	24	**17.40**	3.57
	boys	6	12	19	**15.83**	2.93
school 3	girls	8	7	20	**12.75**	3.85
	boys	19	9	24	**16.79**	4.59

Table 2: Descriptive statistics of students´ chemistry self-concept

The differences regarding the students´ chemistry-related self-concept are smaller but point into the same direction. The minimum score of 5 indicates a very low, the maximum of 25 a very high chemistry self-concept.

At the end of the project the same questionnaire will be applied in order to see if there is any change in the students´ motivation and/or self-concept.

Qualitative Data

Sadler et al. (2010) classify the possible learning outcomes of apprenticeship programs amongst others in terms of scientific content knowledge, skills, confidence and self-efficacy, intellectual development, satisfaction and discourse practices.

Regarding *scientific content knowledge* the project is highly interdisciplinary. Of course, students had and have the opportunity to broaden their understanding of chemistry in general, and of acids and bases in particular. The majority of them report that they have the feeling of having learned a lot concerning this matter. One student explained this as follows:

Student 6: “It was a good way of giving us an understanding of acids and bases. Otherwise I wouldn't have looked into it so deeply. Because of the preparation of the interviews the subject became more concrete and less alien.”

But at the same time the students also got to know some aspects of didactic and social sciences, topics that are not normally taught at school. More than three quarters of them described conducting the interview as being beneficial.

Student 22: *"*Above all I found conducting an interview an extremely helpful learning progress. We will probably need these skills quite often in the future but they are not easy to learn. […] It was an important experience to assess one's interviewee and to adjust oneself regarding language and content."

When preparing the interviews many students had expressed their fears of whether the lower secondary pupils would take the task seriously and how they themselves would manage their new role. Afterwards, most of them were pleased and proudly reported on their experience. This is an example of how the learning opportunity contributed to increasing the students´ *self-confidence*.

The students´ reflective papers also account for various *skills* of different categories (Sadler et al., 2010) the students worked on. For example, a student described the research process they went through to collect and analyse the data:

Student 1: "We first had to develop the guidelines for the interview and then interview two groups of pupils. It was not always easy to gain concrete and useful conceptions from the pupils' answers."

Another one depicts the teamwork as challenging:

Student 7: "I once again noticed how difficult it is to work as a group. The group members don't necessarily like each other. Therefore it is even more difficult to get organized as they aren't motivated."

There are also passages in the papers that indicate *intellectual development*. For example, one student reflected on his/her own work attitude and how it was influenced by the project:

Student 7: "We noticed that we didn't have a clue of what we were talking about [acids and bases]. That's how I learned to really involve myself in a topic before working with it."

A teacher pointed out during the interview that the students´ black-and-white thinking was challenged by their work on the Concept Cartoons.

Teacher 2: "One thing the students acknowledged was that they became aware that statements are not always either right or wrong, but some have to be discussed."

As Concept Cartoons are developed to promote argumentation and *discourse practice* in science education, working in a project on Concept Cartoons provides an opportunity to gain experience and skills in these fields.

Unlike extra-curricular apprenticeship programs, student-scientist partnerships work with all students of a class including also the less interested and less talented. That is why *engagement* and *satisfaction* – two factors quite dependent on each other – are crucial. Satisfaction relies on success and success relies on engagement. In accordance with their different general attitudes towards chemistry learning at school, the students´ commitment varied.

Nevertheless, all three teachers noted that some students definitely engaged more than they usually do.

Teacher 2: "Especially those students who are less talented regarding chemistry turned out to be really good in drawing or in meticulously transliterating the interviews. They knew that this is the way to show what they are able to do."

A student reported:

Student 13: "We were able to fulfill the expectations of the project managers because we worked as a group and did not give up even though we had to overcome many obstacles."

The notions that the effort was worthwhile and that the students took pride in their work can be found in the following quote, which is representative of several:

Student 9: "To finally draw the Concept Cartoons was the best and most joyful part of the whole project, maybe partly because we realized what all the work was for. I am very content with the final result!"

CONCLUSIONS AND IMPLICATIONS

The data available half way through the project allows preliminary results and conclusions. These highly rely on the self-reports of the participants, a fact generally criticised by Sadler et al. (2010). Nevertheless, the results suggest that the students did benefit from their involvement in the research on the use and construction of Concept Cartoons for chemistry classes in various ways.

Many of the statements quoted above can be interpreted as indicating a potential learning progress in more than one category. For example, having successfully "*overcome many obstacles*" (S13) helps to foster self-efficacy. Realizing that "*some statements are not always either right or wrong, but some have to be discussed*" (T2) is a sign of increased understanding of the nature of science (NOS).

The overall impact of the student-scientist partnership cannot be evaluated before the end of the program. On the one hand, further learning opportunities will be offered when the students revise their Concept Cartoons and witness and support their deployment in lower secondary school classes. On the other hand, the post-test questionnaire has to be applied and the results have to be compared with the initial findings. In-depth interviews will be conducted with some of the students, and the teachers´ reports need to be evaluated.

However, apart from gains in various specific domains students most certainly have generally broadened their horizons. The project provides insight into disciplines that are not part of the usual curriculum and thus contributes to breaking down structural barriers between school and university.

HOMEWORK MOTIVATION AND ACHIEVEMENT IN CHEMISTRY EDUCATION

Katja Stief[1], Hubertina Thillmann[2] und Elke Sumfleth[1]
[1] University of Duisburg-Essen
[1] Ruhr-University of Bochum

Abstract: Based on the assumption that homework effort is a key factor for achievement and affected by motivation, this study investigates the effect of a systematic variation of homework assignments' features namely context (domain specific, non-domain specific), the treatment of experiment (paper-pencil, hands-on), and level of task demands (low, medium, high) on homework motivation in chemistry education. Therefore, assignments are created and subsequently rated by students with regard to value and expectancy beliefs by means of a questionnaire. Then, a study was conducted within which students were given the assignments for homework.

Keywords: homework, expectancy beliefs, value beliefs, effort, quasi-experimental study, chemistry education

FRAMEWORK

Students tend to put a minor effort in doing their homework, probably considering homework a waste of time. Not only students unwilling to do their homework doubt that time investment into homework pays off, but also researchers have not proved a correlation between time spent on homework and achievement, yet. However, a crucial factor for achievement might be homework effort (Schnyder, Niggli, Cathomas, Trautwein, & Lüdtke, 2006) which might be positively affected (Trautwein & Köller, 2003) by aspects of homework motivation such as value and expectancy beliefs (Eccles & Wigfield, 2002; Wigfield & Eccles, 2000).

Most studies on homework are concerned with homework in general and less emphasis is put on domain-specific aspects and behaviour, although it is supposed to differ depending on the subject. However, Trautwein and Lüdtke (2007) have conducted a study focussing on differences in homework effort with respect to different school subjects using scales deriving from a previously developed homework model (Trautwein, Lüdtke, Schnyder, & Niggli, 2006).

Although a variety of differences in homework behaviour have been investigated, homework behaviour has not been subject to a study investigating domain-specific effects in chemistry education, yet. In this work, the effect of homework characteristics (learning environment) on achievement in chemistry education shall be examined. The study is conducted to answer the following research questions:

1. To what extent may homework assignments in chemistry education embedded into different learning environments positively influence students' motivation with regard to value beliefs and expectancy beliefs?

2. What effect does a variation of value beliefs and expectancy beliefs have on achievement?

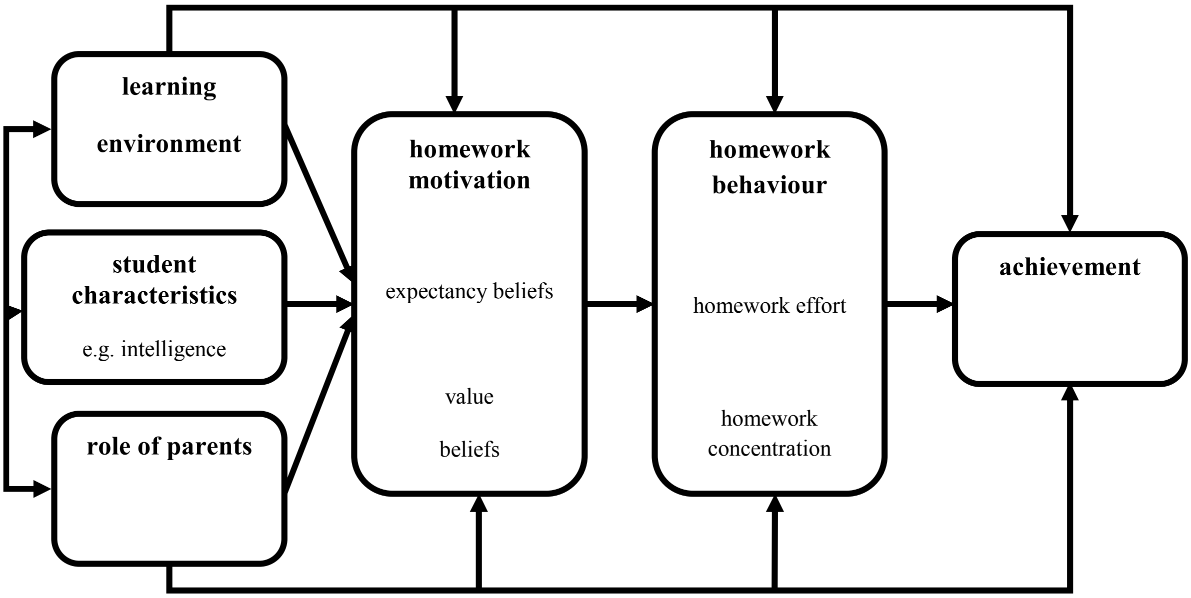

Figure 1: simplified homework model (Trauwein et al., 2006)

METHODS

In order to answer the research questions, the study was conducted in two steps. The first step focuses on answering the first research question. In this phase assignments were created for four lessons out of a sequence of eight lessons and evaluated with regards to motivational aspects. The function of the evaluation was to select assignments to be used in the second phase of the study. The second phase focuses on answering the second research question. In this phase, assignments that are found to differ in students' self-reported value beliefs and expectancy beliefs are given for homework in a course of eight lessons within a framework of a quasi-experimental study. In order to investigate the effect the differences in motivational aspects of the respective assignments have on achievement, achievement data are obtained in a pre-post design.

As situational interest can be increased by contexts perceived relevant by the students (Krapp, 1993, 1999; Krapp & Prenzel 1992; Schiefele, 2001) one of the features being varied is context. Experimental work in general is seen positively (Hofstein, 2004; Hofstein & Lunetta, 2004) and various studies describe that experimental homework is preferred to non-experimental homework (Tiedt, 2006; Vries, Martin, & Paschmann, 2006). Consequently, the assignments created for the four of the eight lessons for the first step of the study vary in (i) context (four non-domain specific contexts, two domain specific contexts = six-fold), (ii) the treatment of experiment (paper-pencil, hands-on = two-fold), and (iii) difficulty (low, medium, high = threefold).

(i) The contexts are generated by stories created for this purpose and narrated formulaically as follows: a protagonist slips into a situation demanding an experiment to be carried out in order to solve a problem.

(ii) To solve the hands-on-experiment assignments an experiment has to be carried out. Accordingly, the paper-pencil variation contains a representation of probable observations and differs from the hands-on-experiment variation in that the represented observation is to be interpreted without carrying out an experiment beforehand. In both cases, the respective observations have to be interpreted and the results are to be evaluated taking the problem to be solved into account.

(iii) The level of difficulty is determined by the complexity of the tasks. It is expected that difficult assignments have a negative effect on expectancy beliefs and assignments perceived as too easy might be considered less worth to be solved.

The resulting 4*6*2*3 = 144 assignments have been rated by a sample of 608 eleventh grade students. Every student has evaluated a set of nine assignments differing in context, treatment of experiments, difficulty level and lesson. Therefore, the questionnaires developed and successfully used by Trautwein et al. (2006, 2007) were adapted for the purpose of rating the particular assignments. To score the respective items, a 4-point Likert-type scale is used ranging from total agreement (1) to total disagreement (4).

The next step was to experimentally investigate whether homework motivation, and thus homework effort and achievement are affected by the characteristics of the homework given. Students were provided with the previously created and rated homework in the course of a sequence of eight lessons. While half the students were given homework containing rather positively rated assignments (intervention group), the other half (control group) received rather negatively rated homework instead. Additionally, the intervention group were offered a choice of homework in the second half of the course in order to examine the effect of choice on achievement. Since deciding between homework offers evokes the feeling of autonomy, a positive effect on the learning progress is anticipated on the grounds of self-determination theory (Deci & Ryan, 2000).

PRELIMINARY RESULTS

Investigating the resulting data set using ANOVA no significant differences between the respective levels of difficulties as well as between the treatments of experiment could be detected. According to the calculated estimated means, the most positively rated context regarding expectancy beliefs is the party context (1.74), while the most positively rated context regarding value beliefs is sports (2.29). However, the most negatively rated context regarding expectancy beliefs (1.90) as well as value beliefs (2.35) is the domain-specific context with a laboratory worker being the protagonist. With regard to context there is a linear contrast between the contexts party and laboratory ($T(138)=-2.263$ ($p<.05$)).

However, assignments including stoichiometric calculations seem to have the strongest effect on motivation ($F(3,140)=45.29$; $p<.01$) and expectancy beliefs are significantly lower, for assignments that require calculations to be performed than for assignment without calculations (linear contrast $T(140)=10.372$; $p<.01$).

Hence, the control group was provided with homework assignments having a laboratory worker as protagonist, while the intervention group was assigned homework with party context. Homework assignments having sports as context were used in the second part of the intervention in which the intervention group was provided with a choice of 4 assignments for each lesson. In the intervention study, the assignments of the control group as well as the assignments of the intervention group were rated similar to the exploration study. Still another similarity between students participating in the intervention study and the exploration study is the extent to which they report to put an effort in doing their homework for chemistry in general and also for the subjects English, mathematics and physics. Across all subjects, the reported effort correlates with expectancy beliefs ($.392 < r < .494$; $p < .05$) as well as with value beliefs ($.450 < r < 495$; $p < .05$). A t-test for independent samples shows a difference in the effort reported for chemistry compared to physics with chemistry being the subject with higher efforts reported ($t(873)=2.374$; $p < .05$). In both studies, the parents are more involved in the homework process when homework is for English or mathematics, although parents of eleventh grade students are less involved in the homework process than parents of ninth grade students, when students do their homework for chemistry ($t(770{,}589)=-2{,}254$; $p<.05$), English ($t(741{,}205)=-4{,}766$; $p<.05$) and mathematics ($t(754{,}871)=-2{,}574$; $p<.05$).

CONCLUSIONS

On the whole, the homework assignments and the homework situations in different subjects are rated similarly in both studies. Also despite of the differences in age, the effort put into homework for English and mathematics is similar, but parental involvement is different. The older the students, the less are the parents involved into doing homework. This finding is well in accordance with previous studies (Kieren, 2008). All in all, the preliminary result are also well in accordance with the underlying homework model (Trautwein et al., 2006)

THE SECRETS OF OUTDOOR GAMES AND THE LAWS OF KINEMATICS

Ekaterina Teteleva[1] and Sergey Bogdanov[2]
[1] Karelian State Pedagogical Academy, Petrozavodsk, Russian Federation
[2] Karelian State Pedagogical Academy, Petrozavodsk, Russian Federation

Abstract: Outdoor activities can play an essential role in studying physics. The construction of a content and learning environment based on everyday life experiences of students remains an appealing challenge for teachers: a careful and thorough didactical analysis is necessary to put forward each concrete case or teaching module. In this paper an example of designing a case based on a non-traditional set of exercises for traditional kinematical issues is presented. An outdoor game is used as a main resource for coherent content-context designing.

The content components of the case include traditional kinematical issues: “translational and rotational motion”. Usually these issues are not so easy for students and the traditional sets of exercises often look boring or artificially sophisticated for them. One of the ways to overcome this difficulty is to use the well-known traditional games as an element of learning environment. Students’ experience in and inspiration towards some well-known activity games are very important resources. The purpose of this study was to analyze the didactical potential of ancient outdoor games and to work out a non-traditional set of exercises appropriate for organizing individual action-research studies for small groups of students.

Keywords: outdoor activity, kinematics, content-context designing.

Background

During the last decade the interest of students in science education in most developed countries has been falling crucially (Fig.1). In general it’s the result of the great social, cultural and economical changes in modern society despite the fact that in many countries the development of a knowledge based society is declared as a strategic goal (NSB, 2004).

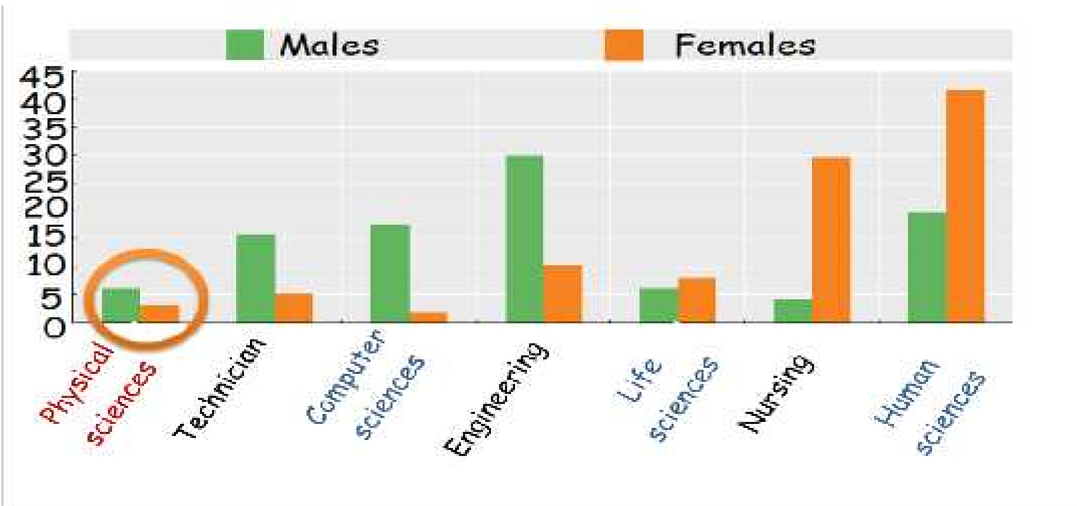

Figure 1

The teachers’ and scientists’ communities make huge efforts to overcome this contradiction, contribute a lot to improve learning environment. In particular, new methods and approaches based on thorough analysis of the context, cultural and psychological aspects of learning were carried out in physics education. On the other hand, the problem of *content* remains actual and challenging too. It is proved by the success of research-based schemes of studies, when content and context interplay actively. Among these schemes teaching science outdoors is of special interest (Popov O., Tevel I., 2007). Within this scheme the teacher has a good opportunity to motivate and encourage students, exploring their natural inspiration towards the investigation of the world of everyday life. Science field experiences can be designed and implemented in "natural" areas and urban environments taking into account cultural and historical traditions. One of the resources, still not exploited in the proper way, is connected with traditional games.

Undoubtedly, most of us – students and teachers – had played outdoor games, at least in the childhood. Usually, you need a very modest "set of equipment" for such games.

For example, the set for the game «Priest», which is very popular in Russia, includes only a stick and tins (Fig. 2). The idea of the game is very simple: to knock off a tin (or several tins) using a stick.

Figure 2

The position of the player is restricted by the sequence of threshold lines. The starting position corresponds to the line, wich is most distant from the target him.

The successive player has the right to shift his/her position to the next threshold (Fig.3). Typically, children try to stand closer to the target, make the throw with more force and try to use a more lengthy stick. But very often all these tricks don't work properly and the stick misses the target.

It appears that this simple game and its secrets are really good material for introducing and careful analyzing the kinematic laws.

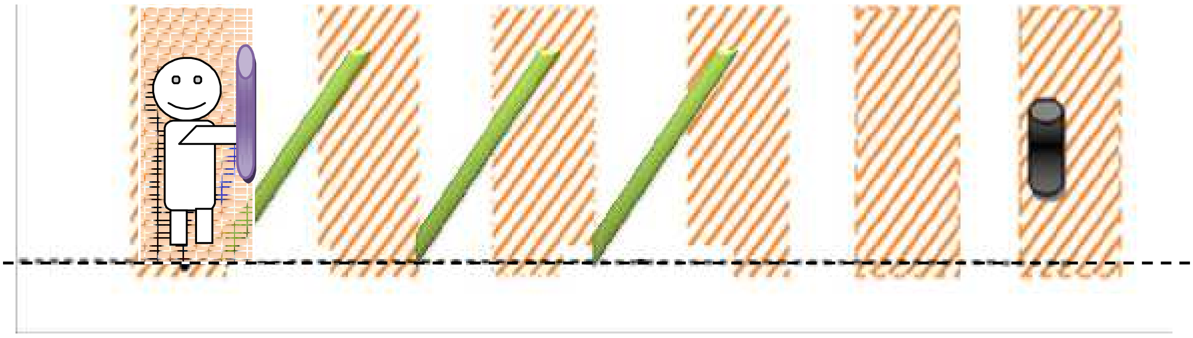

Figure 3

Purpose

The research question was: to analyze the didactical potential of an ancient outdoor game. It is a really hard question - stay in a classroom or go outdoors? It is much more complicated to go outdoors with a class. A teacher must think about a place and equipment, about students' safety, about organization of students' work, because students could just play a game without any reflection. And it could be rainy or windy, etc. So the question is: does a teacher need to make the lesson much more complicated? We decided to risk and go outdoors.

Course design

The course design included three steps:

* Classroom learning. Teacher' explanations, theoretical background.
* Outdoors activities. The students went out door and tried to use different techniques of stick throwing.
* Classroom discussion. Deriving conclusions.

Participants

The investigation was made in the spring of 2011. The target group was the first and the third year students from the department of physics and mathematics.

Methods of the investigation

In the investigation we used both a qualitative research method (observations, interviews) and a quantitative method – a questionnaire. We tried to do triangulation (Berg, 2004) in our research, i.e. we used three different research methods, "lines of sight". We validated the observations by interviews and questionnaire. The similarities in the results that we got using the different methods indicated that the results were reliable.

Classroom learning

The first step of the explanation was the classroom learning. First of all, to discover and explain the secrets of the game one needs to analyze the nature of the motion of the stick by applying the principle of "independence of motions". By taking into account the superposition of traversal and rotational motions, it's easy for students to imagine the qualitative picture for the trajectory of the stick. Moreover, within the secondary school or introductory university physics course it is possible to make accurate calculations. For the beginning it is reasonable to realize the simplest case, when the stick is supposed homogeneous and the throw is obtained only by hand rotation. The correspondent law of motion for every point of the stick is derived directly. The resulting trajectories form a set of cycloid curves, the famous ones which appear in different physics applications (Davydov V, 1989). The real throw is more complicated. Different players use different throws using not only the hand, but also the elbow, shoulder and torso rotation (this set of trajectories of different points of the stick is represented by figure 4).

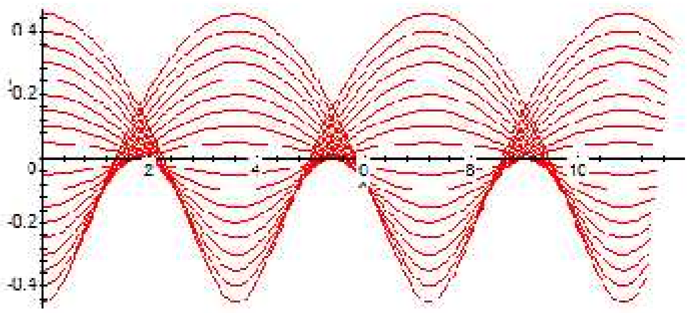

Figure 4

However, any real throw could be represented as a result of the rotation relatively single axis with effective length (the distance between the axis and the center of the stick) and transversal motion. In this case the law of motion takes the form:

$$\begin{cases} x(t) = (l + r)\omega t - r \sin \omega t \\ y(t) = -r \cos \omega t \end{cases}$$

Here r is the distance of the point from the center of the stick, l – the length of the stick, ω - angular velocity. The beginning of the coordinate frame corresponds to the position of the player. The resulting trajectories' form is a set of cycloid curves, which is rather difficult for the students to imagine. So it is reasonable to illustrate stick motion by visualization. The correspondent image sequence is presented on figure 5 for a homogeneous stick; x is the distance which the stick covers. This view of the trajectory is now a little bit easier for students.

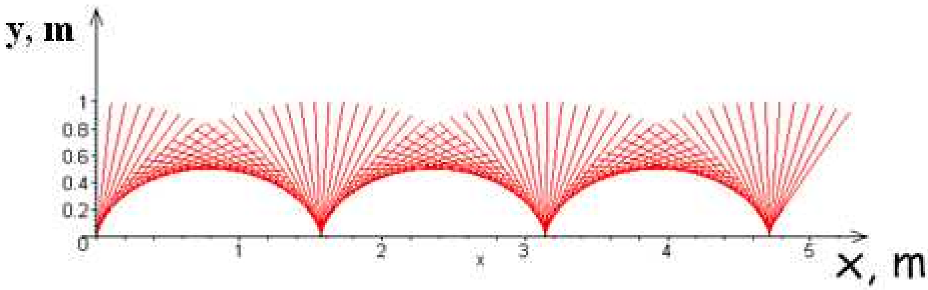

Figure 5

The typical value 1 m is chosen for the parameter l, but of course this value can vary in a wide interval depending on the mentioned parameters of the human body. At the end of the classroom learning a movie was shown to help the students. After that the students received a questionnaire which was "game-oriented". Unfortunately most students failed with their first answers.

Outdoors activities

The second step was the outdoor activities: the students played Priest actively, discussed the results, and tried to use different techniques of the throw. For example:

- Choosing the discrete distances at which the throw will be more successful and checking the dependence of these distances from the length of the stick and the physiological parameters. The trajectory of the stick does not depend on the angular velocity and the force of the throw. Frequently, children try to throw the stick harder or to twist it more rapidly. But soon they realized that it was a misconception. Due to their own experimenting they succeeded in proving that the trajectories have a periodical character with spacing depending on the parameter l. So the discrete set of lines for the most successful throws is individual for each player.
- Knocking off two tins located successively along the axis (Fig. 6).

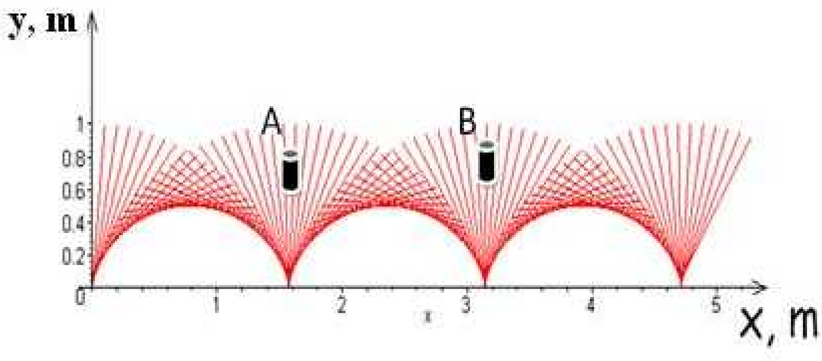

Figure 6

- Experimenting with the "gates" (Fig. 7). What is the minimal distance between these tins for which the stick will fly through the gate? Part of the students could try to calculate it; the other part could try to check it. The result of calculations for a special case of hand throw is: $h_{min} = 0{,}67R$. So the distance between the gate's doors could be about the third part of the stick. The result is even more amazing for the real throw, when shoulders and elbows are involved too. Here the value of is reduced to *l/6* or even less.

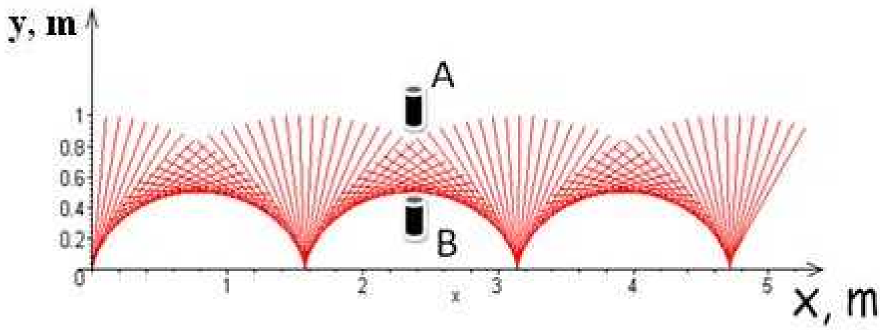

Figure 7

- Aiming at different places near the target in order to check the rule "aim little left for righthanders". The trajectory is asymmetrical. It means that the choice of the impact parameter is very essential. In particular, the player has more chances to succeed if his/her line of aim is slightly shifted to the *left* from the target for *right-handed* people and v.v.

Classroom discussion

The third step was a classroom discussion. During this lesson the students actively discussed their outdoor activities. It is worthwhile to stress that all students without any exceptions actively participated in the discussions. We regard this as the evidence of high communicative potential of the course design.

At the first step of the course designs – classroom learning, the students received a questionnaire which was "game-oriented". As was mentioned above, the qualitative results (at least the percentage of right answers) were rather low. The crucially improved version of the answers, inspired by students' outdoor experience, was one of the essential results of the mutual discussion. It proves that the course design appeared to be a good tool for students' recognition and of overcoming their original misconceptions.

It was also a pleasure and joy for us as the teachers to observe the process of generation of various creative thoughts during the discussion. The students actively shared the ideas on further “field experiments” and demonstrations. In particular they offered the possible new variants of the game, with variable parameters of the stick, with alternative geometry of the yard and displacement of tins.

Conclusions

- Students’ experience in and inspiration towards some well-known activity games are very important resources for Science course design.
- It is not so easy for the teacher to organize outdoors lesson. First of all, one must think about a place and equipment, about students’ safety; besides to take account of rainy – windy weather forecast and so on. Besides the main challenge for the teacher is to organize properly the students’ work, namely to turn “the just playing game” process into intriguing physical experiments, with reflections and planning. But these efforts will return with hundredfold.
- The tools for realizing this learning environment are extremely cheap or even free, including only the access to nature and very modest “set of equipment” – only a stick and several tins.
- The outdoors activities are powerful instruments for creating a productive learning environment.
- The construction of schemes based on everyday life experience of students remains an appealing challenge for teachers.

PREDICTORS OF CHEMISTRY SELF-EFFICACY AMONG COLLEGE STUDENTS

Esen Uzuntiryaki Kondakci[1], Yesim Capa Aydin[1], Zubeyde Demet Kirbulut[1] and Michael E. Beeth[2]
[1]Department of Secondary School Science and Mathematics Education, Faculty of Education, Middle East Technical University, Turkey
[2]College of Education and Human Services, University of Wisconsin Oshkosh, USA

Abstract: Self-efficacy beliefs determine students' choices in performing science-related tasks, their efforts to do them, and their persistence and perseverance when faced with difficulties. Because of the task and domain specifity of self-efficacy, this construct should be interpreted within a specific domain. There is a gap in the literature which examines students' self-efficacy beliefs in specific areas of science such as chemistry. The purpose of this study was to investigate the contribution of academic achievement, the number of chemistry courses taken, involvement in a chemistry project, expected grade, and gender to college students' chemistry self-efficacy beliefs. Data were collected by administering the College Chemistry Self-Efficacy Scale (CCSS) developed by Uzuntiryaki and Capa Aydin to 488 college students. The CCSS consisted of 21 items in three dimensions: self-efficacy for cognitive skills (SCS), self-efficacy for psychomotor skills (SPS), and self-efficacy for everyday applications (SEA). The results of the Multiple Linear Regression analyses indicated that the number of chemistry courses taken, involvement in a chemistry project, and expected grade were significant predictors for SCS; the number of chemistry courses taken was significant predictor for SPS, and the number of chemistry courses taken, involvement in a chemistry project, and expected grade were significant predictors for SEA.

Keywords: self-efficacy, multiple linear regression, chemistry, college students, science education

INTRODUCTION

Self-efficacy is defined as "beliefs in one's capabilities to organize and execute courses of action required to produce given attainments" according to social cognitive theory, proposed by Bandura (Bandura, 1997, p. 3). Bandura (1986, 1997) posited that self-efficacy beliefs developed as a result evaluation of four sources: Mastery experiences, vicarious experiences, verbal and social persuasion, and physiological state. Research studies conducted in the past decades explored the importance of self-efficacy beliefs in education by showing the relationship between self-efficacy and academic achievement, engagement, self-regulation, and career choice (Britner, 2008; Pajares, Britner & Valiante, 2000). In addition, self-efficacy beliefs determine students' choices in performing science-related tasks, their efforts to do them, and their persistence and perseverance when faced with difficulties (Bandura, 1986). In line with the Bandura's argument related to association between self-efficacy and students' choices in performing science-related tasks, Dalgety and Coll (2006) reported that first-year chemistry students with high self-efficacy beliefs intended to study chemistry at second-year level. Related literature includes contradictory research findings in terms of gender difference. For instance, female students reported stronger self-efficacy in science classes than males (Britner, 2008), while females were less efficacious in studies conducted by Anderman and Young (1994) and Britner (2008). On the other hand, Capa Aydin and Uzuntiryaki (2007) indicated that there was no significant difference by gender. Because of the task and domain specifity of self-efficacy, this construct should be interpreted within a specific domain (e.g., science, chemistry, physics, etc.). In the literature, there are many studies focused on students' science self-efficacy beliefs in domain general areas. However, there is a gap in the literature which examines students' self-efficacy beliefs in specific areas of science such as chemistry. The present study aimed at investigating the contribution of academic achievement, the number of chemistry courses taken, involvement in a chemistry project, expected grade, and gender to college students' chemistry self-efficacy beliefs. It is hoped that identifying these factors will be helpful in designing instructional strategies that promote self-efficacy.

METHODS

Sample

The sample consisted of 488 students in a mid-western college in USA. Of 488 students, 269 of them were female and 219 of them were male. Their ages ranged from 17 to 48 with a mean value of 20.2 and a median of 19.

Instrument

In this study, data were collected using the College Chemistry Self-Efficacy Scale (CCSS) developed by Uzuntiryaki and Capa Aydin (2009). The scale consisted of 21 items in three dimensions: self-efficacy for cognitive skills (SCS), self-efficacy for psychomotor skills (SPS), and self-efficacy for everyday applications (SEA). Findings of confirmatory factor analysis provided evidence for the three-factor structure of the CCSS for USA sample with relatively satisfactory fit indices (CFI = 0.97; NNFI = 0.97; RMSEA = 0.10). Analysis of internal consistency reliabilities yielded Cronbach alpha coefficients of 0.87 for self-efficacy for cognitive skills, 0.92 for self-efficacy for psychomotor skills, and 0.86 for self-efficacy for everyday applications, indicating satisfactory reliability. In addition, a demographic form was included asking participants to report their gender, age, GPA, the number of chemistry courses taken, whether or not they participated in a chemistry project, and expected grade (A, B, C, etc.).

Data analysis

In order to investigate the role of academic achievement, the number of chemistry courses taken, involvement in a chemistry project, expected grade, and gender in predicting college students' chemistry self-efficacy beliefs, three separate Multiple Linear Regression analyses were conducted. The outcome variables were self-efficacy for cognitive skills, self-efficacy for psychomotor skills, and self-efficacy for everyday applications. GPA, gender, number of chemistry courses taken, involvement in a chemistry project, and expected grade were predictor variables. Expected grade variable was dummy coded taking grade A as a reference level. Dummy 1 refers to pairwise comparison between grade A and grade B. Dummy 2 refers to pairwise comparison between grade A and grade C.

RESULTS

Multiple regression analysis for SCS

Results indicated that the model explained 18.7% of the variation in SCS ($F(6, 348) = 13.30$, $p<0.05$). The number of chemistry courses taken ($\beta = 0.155$), involvement in a chemistry project ($\beta = 0.113$), and expected grade ($\beta = 0.328$ for dummy 1, $\beta = 0.366$ for dummy 2) were significant predictors of SCS. Table 1 presents unstandardized coefficients (B values and standard error) and standardized coefficients (β) for the predictors.

Table 1. Unstandardized and standardized coefficients for the predictors for SCS

	B	Std. Error	β	Sig.
(Constant)	7,354	,681		,000
gender	,086	,118	,037	,466
chemcour	,093	,030	,155	,002*
gpa	-,065	,141	-,026	,648
chemproj	-,431	,185	-,113	,020*
DUMMY2	-1,100	,193	-,366	,000*
DUMMY1	-,764	,137	-,328	,000*

*p<0.05

Multiple regression analysis for SPS

Results showed that 3.7% of the variation in SPS was explained by the model ($F(6, 348) = 2.22$, $p<0.05$). The number of chemistry courses taken ($\beta = 0.128$), was the only significant predictor of SPS (see Table 2).

Table 2. Unstandardized and standardized coefficients for the predictors for SPS

	B	Std. Error	β	Sig.
(Constant)	8,178	,890		,000
gender	-,036	,154	-,013	,813

chemproj	-,404	,241	-,088	,095
DUMMY2	-,350	,252	-,097	,165
DUMMY1	-,272	,179	-,097	,129

*p<0.05

Multiple regression analysis for SEA

The model accounted for 10.2% of the variation in SEA ($F(6, 348) = 6.62$, $p<0.05$). The number of chemistry courses taken ($\beta = 0.185$), involvement in a chemistry project ($\beta = 0.134$), and expected grade ($\beta = 0.198$ for dummy1, $\beta = 0.193$ for dummy 2) were significant predictors of SEA (see Table 3).

Table 3. Unstandardized and standardized coefficients for the predictors for SEA

	B	Std. Error	β	Sig.
(Constant)	7,273	,836		,000
gender	,049	,144	,018	,733
chemcour	,130	,037	,185	,000*

gpa	-,127	,173	-,044	,465

DUMMY2	-,676	,236	-,193	,004*
DUMMY1	-,538	,168	-,198	,002*

*p<0.05

CONCLUSIONS AND IMPLICATIONS

This study investigated the role of the academic achievement, number of chemistry courses taken, involvement in a chemistry project, expected grade, and gender in predicting college students' chemistry self-efficacy beliefs. Results indicated that the number of chemistry courses taken, involvement in a chemistry project, and expected grade were significant predictors for SCS; the number of chemistry courses taken was significant predictor for SPS, and the number of chemistry courses taken, involvement in a chemistry project, and expected grade were significant predictors for SEA. The number of chemistry courses taken was the only variable which predicted chemistry self-efficacy in all three dimensions (SCS, SPS, and SEA). In addition, involvement in a chemistry project significantly predicted the SCS and SEA. These results were in line with Bandura's claim which states that the more experience with a task students have, the higher self-efficacy they have (Bandura, 1986; Bandura, 1997). Britner (2008), Britner and Pajares (2006) and Lent, Lopez, and Bieschke (1993) also found similar results. On the other hand, involvement in a chemistry project was not a significant variable for SPS. This study did not explore the type of chemistry projects in which students engaged; therefore, it is not possible to identify whether the chemistry projects addressed to all skills (cognitive and psychomotor) in chemistry. In terms of expected grade, there was a significant difference in favor of high grades, A. As students expect higher grades in chemistry courses, they reported higher efficacy. It is crucial for instructors to be aware of the self-efficacy sources and the contribution of variables such as academic achievement and gender to students' self-efficacy beliefs to design their courses effectively. This study was limited in terms of ways of collecting data. All of the variables were self-report measures, which limits the interpretability of results. Further research utilizing qualitative method is warranted to elaborate students' experiences and their self-efficacy beliefs.

CHARACTERISTICS OF REAL LIFE CONTEXTS AND THEIR INFLUENCE ON STUDENT INTEREST IN LEARNING CHEMISTRY

Helena van Vorst[1] and Sabine Fechner[2]
[1] University of Duisburg-Essen
[2] Leibniz University Hannover

Abstract: Over the last thirty years, an increasing number of approaches for the development and implementation of context-based curricula has emerged all over the world. Their aim is to raise student interest in chemistry by pointing out the relevance chemistry content and its application outside school. Although different studies have shown a positive effect on student interest and motivation if real life contexts are integrated, a more differentiated look at results shows that they vary significantly depending on the chosen context.
Based on this background, the presented study analyzes the influence of context characteristics on student interest in learning chemistry. When these characteristics have been elaborated, defined and substantiated by a rating and a student inquiry, student interest in contexts with specific characteristics will be investigated. The results of the rating can be used as a basis for the construction of a questionnaire to validate the constructed contexts with the help of a student inquiry. Contexts with a clear attribution of the respective characteristic could be selected for the interest investigation.

Keywords: student interest, context-based learning, context characteristics

PURPOSES

As interest and motivation are central objects of educational research, their role in successful learning processes has already been well-investigated (Krapp, 2002). In their meta-analysis, Schiefele, Krapp and Winteler (1992) reported a correlation of r = .30 between interest and learning achievement. Against this background, the results of large-scale interest studies in natural sciences, especially in physics and chemistry, show an alarming status quo. A national cross-section analysis, conducted by the IPN in Germany, for example, make obvious that physics and chemistry are the most uninteresting subjects, especially for girls (Hoffmann, Häußle, Lehrke, 1998). Over-loaded curricula with an inadequate emphasis and an acquisition of isolated facts without relevance and transfer to everyday life lead to a lack of interest (Gilbert, 2006).
Since the beginning of the 1980s, Science-Technology-Society, context-based or the more recent socio-scientific issues-based approaches have developed new curricula and learning materials by embedding scientific contents in out-of-school contexts. The basic idea is to point out the relevance and applicability of these contents in order to raise student interest and increase achievement.
However, a systematic and category-based selection of the chosen contexts cannot be found in any of the approaches. How and why a context is chosen does not become clear.

Although a large number of studies could verify a positive effect on student interest by using contexts in scientific education (e.g. Ramsden, 1997), a closer look at the results of large-scale interest studies, like the international SAS- or ROSE-study, reveal that interest varies significantly depending on the chosen context. Figure 1 illustrates this issue with the help of exemplary results from the SAS-study.

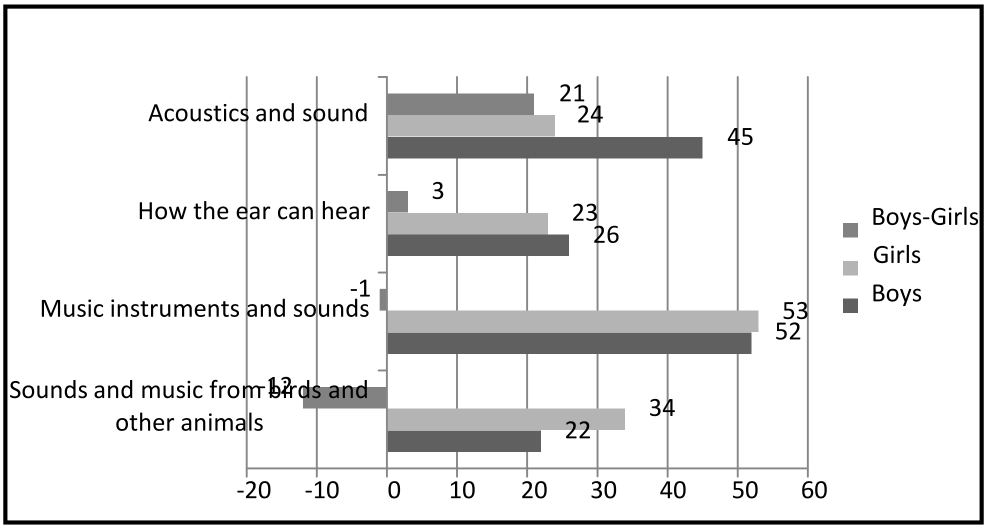

Fig. 1: Interest in different contexts in the physical content *acoustics* (Sjøberg, 2000)

Consequently, the question arises, which specific characteristics make a context interesting for students. The presented study deals with this central question.

THEORETICAL BACKGROUND

Interest and Context-Based Learning

Based on Krapp (1992), interest emerges from a specific interaction between a person and an object, an activity or a field of knowledge. It is composed by a value-related valence, specifying the quality of personal significance, and a feeling-related valence, which is determined by positive experiences while being engaged in an activity. Interest can be "[…] generated primarily by certain conditions and/or concrete objects (e.g. texts, film) in the environment" (Krapp, Hidi, Renninger, 1992, p. 8). Hence, it is caused by external factors and is limited to a specific situation (*situational interest*). *Individual* or *personal interest* is determined by the overlasting dispositional structure of the person. The engagement in the area of individual interest does not need an external stimulation and does not depend on a specific situation.

In a concrete learning situation, the teacher cannot control the students' incoming personal interest but can rather influence situational interest by changing the interestingness of the object. This can be achieved by the chemical content itself, by the chosen activities, or by learning materials. An additional possibility is an adequate embedding of the content in an interesting context. Bennett and others (2005) have evaluated the effectiveness of this approach by comparing teachers' views. Teachers, following the context-based approach *Salters Advanced Chemistry* have reported continuing and increased interest and motivation in their courses as compared to teachers following traditional chemistry education. Additionally, Ramsden (1997) compared statements of students about their experiences during their chemistry courses. His results reveal that students who have attended a context-based course, are especially interested in the relation to everyday life. Fechner (2009) found similar results.

She conducted an intervention about five lessons to compare the effects of context-oriented learning materials with traditional materials on students' interest and learning achievement. Within her study, an increased situational interest was induced by real life contexts. Additionally, it mediated an increased learning achievement. As Fechner has used different contexts for each lesson, her results also show significant differences in students' interest and achievement depending on the context.

Context Characteristics

Taking a look at the literature of different context project groups all over the world, various characteristics for the specification of contexts can be found. Figure 2 gives an overview of the central context characteristics. As *relation to everyday life, topicality* and *uniqueness* were extracted for further analysis, these characteristics are depicted in the foreground.

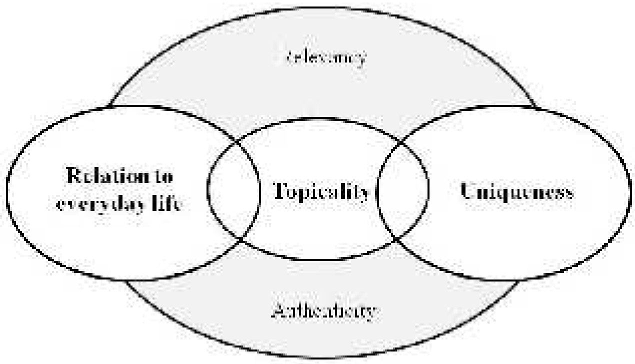

Fig. 2: Context characteristics

To achieve *relation to everyday life* in learning materials, objects of the immediate environment of the students, characterized by familiarity and normalcy, can be used as a context. The opposite alternative is using uncommon objects, which are beyond the students' immediate environment, so that they are not familiar with them. Thereby, the characteristic of *uniqueness* is fulfilled. Moreover, normal or unique objects can be topical, as they are actually published by the media or determined by the present season or an approaching holiday. This issue is represented by the characteristic of *topicality*.

By considering these categories, the characteristics of *relevancy* (e.g. Kasanda et al., 2005) and *authenticity* (e.g. Parchmann, Ralle & Di Fuccia, 2008) should be guaranteed as well. Considering a simplified definition of *relevancy* in the philosophy of language, it is determined by a specific interaction between the student and its environment. With respect to this, the relevant object cannot be seen as an individual entity but is given significance by its environment (Sperber & Wilson, 2006). Within the PISA-study personal, social and global relevance are distinguished (Schleicher, 2001). According to Krapp's concept of interest, personal relevance represents the value-related valence of interest, which leads to situational or individual interest. Hence, personal relevance can be seen as an individual personality trait and can hardly be realized as a context characteristic for learning materials. Consequently, only social and global relevance are considered as context characteristics for the presented study.

The characteristic of *authenticity*, another central characteristic in the literature, is the perceived genuineness of the object. Furthermore, authentic contexts are determined by a certain extent of *complexity* and, hence, provide different alternatives of dealing with the context. Finally, it is important to adapt a context to the students' age, to the curriculum and other general conditions of school (Bayrhuber et al., 2007), which has been summarized by the category *adaptivity.* For the presented study the two categories of *complexity* and *adaptivity* are standardized by a manual and will not be varied systematically.

METHODS

The presented context characteristics are basic for the analysis of the research aim. Therefore, a detailed operationalization of the characteristics is necessary. Hence, the study is divided into two project phases: (1) the operationalization of the characteristics and (2) the analysis of their influence on student interest. The emphasis of the following paragraph is placed on the first project phase, as this represents the current status of work.

Project Phase 1

Initially, it was necessary to determine the characteristics for the description and categorization of contexts, as specified in the context literature. The resulting categories are introduced above. As a manual for context construction provides information on the right amount of *adaptation* and standardizes the level of *complexity* of each context used in this study, these characteristics have not been included in Figure 2.

The operationalization of the main categories *relation to everyday life, topicality* and *uniqueness* has been realized by formulating paraphrasing statements and adjectives as keywords. Two methods were intended to validate them: a rating with colleagues from educational research and student teachers, and a student inquiry.

For the first rating, 35 paraphrasing statements (e.g. *'This is a common object for me.')* were formulated. The inquiry was conducted with 72 participants in November 2010. During the inquiry, the raters had to decide which characteristic is paraphrased by the respective sentence. An additional approach, the semantic differential, was used for the validation of the keywords. As *relation to everyday life* and *uniqueness* are two opposite categories, their adjectives were subsumed in one scale for the semantic differential.

For the student inquiry, 60 exemplary contexts were constructed with the help of the operationalized characteristics. The chosen contexts are all based on organic chemistry content.

	Topicality	
	Yes	*No*
Relation to everyday life	15 context	15 context
Uniqueness	15 context	15 context

Fig. 3: Design for the context construction

The paraphrasing statements were combined in a questionnaire and the contexts were distributed to different assessment forms with the help of a multi-matrix sampling. Each assessment form includes six different contexts. 592 students of the ninth grade of upper secondary schools (German *Gymnasium*) in North Rhine-Westphalia have filled in one questionnaire, consisting of the paraphrasing statements, for each exemplary context. Contexts with a clear attribution of the respective characteristic could be selected for the second phase of the project.

Project Phase 2

In the second project phase, the interestingness of specific contexts will be analyzed. Therefore, a second student inquiry will be conducted. 24 selected contexts (6 contexts for each cell) from the first project phase will be distributed to different assessment forms again. A questionnaire about the interestingness of each context will be administered to 600 ninth-grade students of upper secondary schools.

RESULTS AND DISCUSSION

Data from the first validation was analyzed with the help of the statistics software SPSS®. The data analysis of the paraphrasing statements has shown an inter-rater agreement of κ=.918. Data on the relative frequency of selection was used to determine the final statements for each context category, which were combined in a questionnaire for the first student inquiry. Five statements were selected for each characteristic. For the characteristics *relation to everyday life* and *topicality* phrases with a relative frequency of 95 % and more were selected, for the characteristic *uniqueness* five phrases with a relative frequency of 91.5 % and more could be chosen.

In order to select keywords for the semantic differential, pairs of antonyms with a relative frequency of more than 80% have been chosen. Additionally, a univariate analysis of variance has been calculated for each pair to see, whether the pair was able to differentiate between the characteristics in a significant way. Based on this, five pairs of adjectives per scale could be selected for the student inquiry. The internal consistency estimates of the composed scales are α = .83 for *relation to everyday life/uniqueness* and α = .80 for *topicality.*

A preliminary data analysis of the first student inquiry was conducted with the help of the Rasch-model. Therefore, the software Winsteps® was used. As the items for *relation to everyday life* and *uniqueness* can be seen as two opposite poles of one scale, they could be combined for the following analysis. The two resulting scales (one scale for *relation to everyday life/uniqueness* and one scale for *topicality*) were entered into the analysis as separate dimensions.
In order to analyze the data of the paraphrasing statements a rating scale model was calculated. An analysis of the category structure showed that the chosen 4-point Likert-scale fits the Rasch-model (Linacre, 2011). Table 1 shows some general statistical values for the three dimensions:

Table 1: Statistical values for the dimensions of the paraphrasing statements

		Relation to everyday life/ Uniqueness	Topicality
	Sample Size	592	592
Item:	Reliability	.95	.95
	Separation	4.39	4.32
Person:	Reliability	.87	.84
	Separation	2.56	2.28
	Raw variance explained by measures	54,5 %	43,0 %

For the analysis of the semantic differential a partial credit model was used. During the analysis of the category structure it became obvious that the chosen 7-point Likert-scale was not able to fit the Rasch-model. Hence, it was necessary to combine some of the steps. A reanalysis showed that a 3-point Likert scale for *relation to everyday life/ uniqueness* and a 6-point Likert scale for *topicality* were able to fit the Rasch-model. Table 2 gives an overview on the general statistical values for the semantic differential:

Table 2: Statistical values for the dimensions of the semantic differential

		Relation to everyday life/ Uniqueness	Topicality
	Sample Size	592	592
Item:	Reliability	.94	.94
	Separation	4.05	3.89
Person:	Reliability	.78	.86
	Separation	1.90	2.45
	Raw variance explained by measures	45,1 %	37,5 %

The main aim of the data analysis was to verify the supposed attribution of the characteristics and to select contexts with a clear characteristic attribution for the following inquiry. This aim was realized with the help of an item map for each scale. One can assume that contexts with a clear attribution of the according characteristic are located at the bottom of the item map, because it was easier for students to relate the characteristics to these contexts (Bond & Fox, 2001). Based on this assumption, six contexts for each cell in Figure 3 could be selected for the second student inquiry. As *topicality* of contexts changes in a quite short period of time, it was necessary to construct ten new contexts for the characteristic *topicality.* In order to control the characteristic attribution for these new contexts, a shorten version of the questionnaire consisting of the paraphrasing statements will be added to the interest questionnaire for the second student inquiry.

EVALUATION OF EDUCATIONAL DESIGN METHODOLOGY UTILIZING CONCEPT MAPPING

Veli-Matti Vesterinen, Johannes Pernaa and Maija Aksela
Unit of Chemistry Teacher Education, University of Helsinki, Finland

Abstract: One goal of educational design research is to provide guidelines for the design process. This paper reports on our on-going work on the development of such guidelines by evaluating the design procedure of a pre-service chemistry teacher education course on models and visualization. In the design of the course, the concept maps were utilized as interactive road maps for coordination and documentation of the co-operative development of the design solution. Description of the roles and collaboration between the developers in the design process are presented as a design narrative based on the analysis of semi-structure interviews of three course developers. The evaluated design process had six phases: (i) establishing goals for the design procedure, (ii) evaluation of the initial design solutions, (iii) collaborative construction of the design solution, (iv) implementation of the design solution, (v) evaluation of the design solution, and (vi) evaluation of the design procedure. During the course, the concept map created during the co-operative construction of the design solution was used as a summary of the objectives of the course, management tool, and description of the design process. Based on the results, the presented design methodology is a promising way of utilizing concept maps in coordinating the co-operation of multiple designers in educational design-based research.

Keywords: design research, design based research, concept maps

BACKGROUND AND RATIONALE

For the past 20 years, several papers have discussed educational design research (e.g. Bell, Hoadley & Linn, 2004, Brown, 1992; Cobb, 2001; Dede, 2004; Edelson, 2002; Juuti & Lavonen, 2006). In design research the research-based development is carried out in a real-world situation systematically, flexibly and iteratively through continuing evaluation and expertise of various interest groups (Wang & Hannafin, 2004).

Daniel Edelson (2002) describes three elements of design research: (i) the *problem analysis* characterizes the goals and opportunities of the design as well as the challenges and constraints it has, (ii) the *design solution* describes the resulting design, and (iii) the *design procedure* specifies the processes and people that are involved in the development of the design. According to Edelson, design research produces three types of theories corresponding with these elements: (i) *domain theories* are generalizations of some portion of the problem analysis, (ii) *design frameworks* describe the characteristics of a successful design solution, and (iii) *design methodologies* provide guidelines for the design process.

One possible way to organize, to visualize, and to document a design process is to use concept maps. Concept maps are graphical teaching, learning, evaluation, and presentation tools that were devised as a device of Ausubel´s (1968) theory of meaningful learning. Concept mapping helps organize concepts related to the topic, shows interrelationships among concepts, and illustrates how the concept structure of the topic is constructed (Novak 1998).

As design research has tended to focus on descriptions of design frameworks and domain theories rather than on developing design methodologies, there is a need for new approaches in design procedures. This paper reports on our on-going work on the development of an educational design methodology utilizing concept mapping.

METHOD

In this study, the design procedure of a pre-service chemistry teacher education course on molecular modelling is evaluated by providing a description of the process for pedagogic course design as well as the roles and collaboration of the developers (see Edelson, 2002). A researcher, who did not take part in the design and development of the course, interviewed the three teachers responsible for the course. In semi-structured interviews, these co-developers were asked to describe the design procedure and their role in it, and how they utilized concept mapping in the design and implementation of the course.

Design narrative is a comprehensive description of the whole design process. It explains design conditions, decisions, goals, challenges, and results and is usually created by the developers (Bell et al., 2004; Juuti & Lavonen, 2006). In addition to interviews, the results presented in this study are based on the published initial design narrative written by the developers (Pernaa, Aksela & Västinsalo, 2010).

By qualitative content analysis of the interviews and initial design narrative, a new design narrative was created, focusing on the design methodology, the roles of the developers and the use of concept mapping in the design process.

The questions driving this study were:

(1) How the co-developers collaborated during the design process?

(2) How the roles the three co-developers assumed contributed to the design process?

(3) What purposes concept mapping served in the design process?

Role of Researchers

Second and third authors worked as co-developers and teachers of the course. To objectively analyse the roles developers assumed in the design process, a decision was made that someone who had not worked on the course should make the interviews and analysis. This was the case, as before the interviews the first author had no previous affiliation with the course. However, as the first author is working in the same teacher education unit, the authors recognized there is a possibility for bias, as even the first author has vested interest in the program.

Although the evaluation was done solely by the first author, two co-developers (second and third author) contributed to writing the final design narrative presented here. To ensure the credibility of the results (see Lincoln & Cuba, 1985), a member check was carried out by providing also the third co-developer with the results and conclusions for comment.

RESULTS

Collaboration during the design process

Based on the interviews and initial design narrative (Pernaa et al., 2010) the design process had six phases: (i) *establishing goals for the design procedure*, (ii) *evaluation of the initial design solutions*, (iii) *collaborative construction of the design solution*, (iv) *implementation of the design solution*, (v) *evaluation of the design solution*, and (vi) *evaluation of the design procedure*.

The first phase was not reported in the initial design narrative and the developers did not explicitly discuss the goals of the design procedure. Every developer saw the need for improving the design solution, but at least one of the developers was not aware of the goal of developing the design process as well as the design solution. This caused some problems during the later phases. For example the initial problem analysis and the changes made to the design solution during the implementation were not adequately documented, as all the developers were not aware on how the documentation would be used in the evaluation of the design.

To evaluate the initial design solutions, the developers got acquainted with the feedback and materials from the previous implementations of the course. Based on this problem analysis describing the goals, needs, and opportunities presented by the design context, the developers worked collaboratively to produce a description of the design solution. The concept map was used as a tool for documentation and visualization in constructing a consensus design solution. Concept map created by one of the developers was used as a root model, where all changes, solutions and challenges were documented. The process is visualized in figure 1.

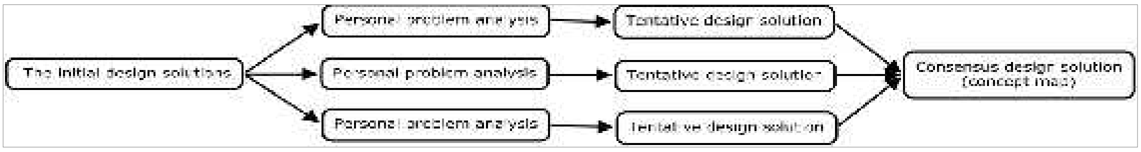

Figure 1. Evaluation of the initial design solutions and the collaborative construction of the design solution.

Roles of the co-developers and concept mapping in the design process

The different roles of the three developers were apparent in the construction of the design solution. The developers included a professor responsible for the course, a PhD student working as an instructor on the course for the second time, and a recently graduated teacher with master’s degree in chemistry education.

The recently graduated teacher had been a student on the course previous time the course was held. During the design and implementation of the course, she reflected mainly on her own experiences as a student. Her contributions were mostly concentrated on improving the practicalities of instruction (*e.g.* software tutorials and modelling exercises). She saw the concept map as a tool for coordinating teaching: From the concept map presenting the consensus design solution (see figure 1) she could see what were the objectives of the course and how the teaching responsibilities were divided. Although she participated in analysis of the research data and writing the article reporting the initial design narrative (Pernaa et al. 2010), she did not feel she contributed much to the research part of the design research process. As a newcomer to the development team, she had a hard time evaluating the contributions of the other teachers developers.

The second developer was a PhD student working for the second time as the teacher on the course. He was writing his PhD thesis on the use of design research in chemistry teacher education. As the main author of the initial design narrative (Pernaa et al. 2010), he concentrated on documenting the design process as well as developing the technical aspects of the course. Having the responsibility of coordinating the course and the design research process, he seemed to be very aware of the contributions of the other co-teachers and developers. Although actively involved in the design process, he felt that he should rely on the expertise of the professor on some issues, such as on deciding the overall goals of the course. In his opinion the teaching responsibilities during the course were quite evenly distributed: The professor gave lectures about the more theoretical aspects of the course, while the other teachers were responsible for supervising and evaluating the assignments. With his attention focused on the design research process, he saw the concept map presenting the consensus design solution mainly as the visualization of the design process. As the design research project was part of his PhD thesis, he had the main responsibility in the research project.

The third developer was professor and head of the unit. She had been involved in every implementation of the course since 2003, when the course was taught for the first time. Her contributions to teaching were mostly directed to develop the goals of the course and the division of labour among the teachers. She saw concept map presenting the consensus design solution as an overview of the course design. Her focus on the development of the course was on the students that the pre-service teachers would one day be teaching. As the supervisor of the PhD students she also participated actively in the research process. Although she wanted to support the autonomy of her PhD students and co-developers, and to encourage them to follow their own interests, she also felt that she is ultimately responsible for the quality of the teaching and research. On day-to-day issues of teaching she trusted the judgement of the other teachers and considered their contribution crucial to the final design of the course. For example, the professor noted that the perspective of someone, who had recently been a student on the course, was direly needed to ensure the relevancy of the course in the eyes of the students.

CONCLUSIONS AND IMPLICATIONS

The developers had distinctly different roles in the construction of the design solution. The less experienced teacher educators focused on the practicalities of teaching and research, and the more experienced professor of teacher education focused on the students as future teachers and supporting the other teacher educators in their teaching and research.

Also other researchers have noted the shift of focus from practicalities of teaching to a more student-centred view. Peter Kugel (1993) describes the professional development of university teacher moving from focusing on their own role as teachers, through focusing on understanding of the subject matter they teach and students' ability to absorb what they have been taught, to finally focusing on helping students learn to use what they have been taught and developing independence and autonomy. The roles designers took in the construction of the design solution seems to be related to their experience as teacher educators much in the way described by Kugel. This does not mean, that inexperienced teacher educators are less valuable for the educational design process: Even though the focus seemed to develop through experience, there was a special need for fresh perspectives.

In the implementation phase, the concept map worked as a "road map" or curriculum for the course. The design solution evolved over the course through analysis and formative evaluation: all things described by the initial concept map were not implemented and some additional elements were added on the course curriculum. The concept map had many uses during the implementation. Developers saw it, among other things, as a description of the objectives of the course, management tool, and description of the design process.

Based on the evaluation of the design procedure, concept map is a useful and versatile tool in educational design research. Edelson (2002) points out that constructing a design solution is a process of creating and evaluating alternative solutions from multiple perspectives. Concept maps can be used to decompose the "complex design problem into manageable components" (p. 109). Concept maps can also be utilized during the implementation as interactive road maps documenting the development of the design solution.

The design methodology presented here is a promising way of utilizing concept maps in coordinating the co-operation of multiple designers in a design research process. The use of concept mapping in the design methodology could be developed even further. To ensure that everyone understands the design process and the importance of adequate documentation, there was a need for conversation about the goals of the design procedure. In such a discussion, concept maps could be used in visualizing and documenting the decisions made in establishing the goals for the design procedure.

THE POTENTIAL OF AN OUT-OF-SCHOOL LABORATORY TO IMPROVE THE IMAGE OF PHYSICS AND CHEMISTRY

Susanne Weßnigk[1] *and Manfred Euler*[1]

[1] *IPN – Leibniz Institute for Science and Mathematics Education at the University of Kiel,Olshausenstr. 62, 24118 Kiel, Germany*

Abstract: Over the last years, new approaches have been proposed to increase the quality of science education. Among them, laboratories that promote inquiry based learning by focusing on scientific methods play an important role. The labs are based on the idea that bringing students into contact with authentic research and development may improve the image of science. A negative perception of school science can be considered as one of the major causes for the decreasing percentage of young people majoring in science and technology. Empirical findings show an implicit association of the 'hard' sciences, especially physics, with difficulty, masculinity and heteronomy. Until now, very few investigations have explored ways how the image of physics of adolescent students can be improved.

The aim of this research is to determine the effects of hands-on, practical, cooperative laboratory-based inquiry activities on students' views of science and technology. For this purpose, the development of key affective variables such as self concept, career orientation and the image of physics and chemistry are examined in the context of Baylab plastics, a recently founded laboratory in industry. In this lab students are given the opportunity to cooperate in groups to design and produce a plastic product within one day using state of the art technology for production modern testing equipment. The lab approach promotes many inquiry-based and learner led activities which foster a creative access to material science. The results show that the lab improves the students' self concept as well as their image of science, especially in the domain of physics.

Keywords: image of science, inquiry-based learning, out-of-school laboratory, role of authentic science, technology laboratory

BACKGROUND, FRAMEWORK AND PURPOSE

In many industrialized countries serious concerns have been raised over the status of science education and the decreasing interest of young people for science subjects. In order to react adequately to the economical, social and ecological challenges in an ever-changing world and to keep up the pace of innovation the increasing uptake of science and technology related studies and professions is considered necessary by the majority of industrialized countries.

The current practice of science education is under challenge. For instance, a high portion of scientifically competent students in Germany have little to no interest in science subjects (PISA Konsortium, 2008). Especially, physics has a negative image, associated with attributes such as *abstract*, *dry, demanding* and *ambitious* (Euler, 2001) and with *difficult*, *masculine* and *heteronomous* (Kessels et al., 2006). There are many reasons for the declining interest during adolescence, for example missing reference to everyday life and missing opportunities to engage in meaningful learning (Euler, 2009).

Kessels et al. (2006) define the image as common assumptions about the characteristics and contents of a subject. It is considered as a possible factor for the negative development of interest. Often students think lessons in physics offer fewer opportunities to create innovative ideas (Kessels et al., 2006). They see physics and chemistry as a collection of facts and do not see that discussing, debating and negotiating the meaning of concepts are important factors in the development of scientific knowledge (Driver et al., 1995). A negative image in connection with specific learning difficulties can be considered the major causes for the decreasing percentage of young people choosing science and technology for profession.

In order to promote students' interest and motivation for natural sciences and to increase the level of scientific literacy the European Commission recommends a more student oriented approach to education in the field of mathematics and science. In contrast to the prevailing traditional deductive teaching style, inductive methods like inquiry and experienced based learning are considered more appealing and cognitively activating (Gago, 2004). Inquiry-based learning is regarded as a key factor for improving students' interest and achievement in science (Rocard et al., 2007).

Innovative approaches to inquiry- and discovery-based learning can be implemented more easily in learning environments like out-of-school laboratories because they do not underlie curricular and syllabus restrictions of the conventional school system. Students can be involved in inspiring and activating learning contexts that are relevant for everyday life or touch upon the interaction of science, technology, economy, and social processes. Such learning laboratories that focus on authentic scientific or technological processes prove successful in increasing interest (Euler, 2009). Their program emphasizes on what students know about science and how they experience science and technology in their everyday life. By contrast, teachers seem to focus more on science concepts (Rennie, 2007). Science education in school and out-of-school-settings can be viewed as “two components of one inclusive education system” (Bybee, 2001).

The present project focuses on the question whether an out-of-school-laboratory has the potential to improve students' attitude towards science, especially the image of physics and chemistry. The empirical study is carried out in Baylab plastics, a school lab run by Bayer MaterialSience. This company is part of the Bayer Corporation and produces high performance plastics and polymers. Baylab plastics pursues an innovative and demanding approach to experience based learning in an authentic industry setting. In order to experience a working day in industry students are presented the challenge to develop, create and complete a modern lifestyle plastic product such as a case of a computer mouse, the frame of sports glasses or a plastic spoon. For this purpose they engage in the various facets of the actual production process from research to design and completion, working together in five different teams: Design, Research, Technology, Finance and Communication. The selection of the teams is guided by the students' interest.

In order to solve the challenging task, students have to deploy different skills in design, management, research and technology fields. For example, the research team has to test if the plastic granulate is dry enough for the production process or to check the quality of the product (e.g. examine if the plastic spoon is dishwasher safe). The technology team has to learn about the function of the extruding machine and run the production process. All groups have to become active, ask questions, identify problems and find solutions. Reflection and communication are indispensable for the group work and for the interaction between the groups. Thus, the program aims at experiencing creativity and the diversity of the different approaches in fulfilling complex, mutually dependent tasks in a collaborative endeavor.

RATIONALE

Up to now only a few surveys have investigated ways improving the image of physics and chemistry; there has been no investigation in connection with out-of-school laboratories. Amongst others this survey will determine the effectiveness of an innovative out-of-school-laboratory on the image of 'hard' sciences.

METHODS

The development of the image of physics and chemistry is accomplished through a semantic differential according to the CAEB study (Stahl & Bromme, 2007; CAEB: An instrument of measuring connotative aspects of epistemological beliefs). The scale of the current study corresponds to the CAEB scale, but applies different adjective pairs in part to adapt to the special situation in the laboratory. It embraces seven pairs of adjectives on a six-step-scale: important-unimportant; productive-unproductive; creative-uncreative; dynamic-static; open-closed; progressive-regressive; innovative-conservative. The image of physics respectively chemistry as a school subject and as sciences is differentiated.

17 classes were tested in a pre-post-follow-up survey with paper and pencil. Around 300 mainly 16-18 years old students got the first questionnaire a few days before visiting Baylab plastics (T1). The second one was handed out right after their visit (T2), and the third three months later (T3).

The results are presented on scale and item level.

RESULTS

As shown in Figure 1, Baylab plastics has a significant influence on the image of physics and chemistry. Due to the lab intervention there is a strong shift of the images towards a higher activity level. However, the results are different with respect to the long term effects. Only the image change of physics as a science is stable for more than three months after the lab visit. All other image changes are only short term effects. They fall to lower activity level after the increase due to the lab intervention.

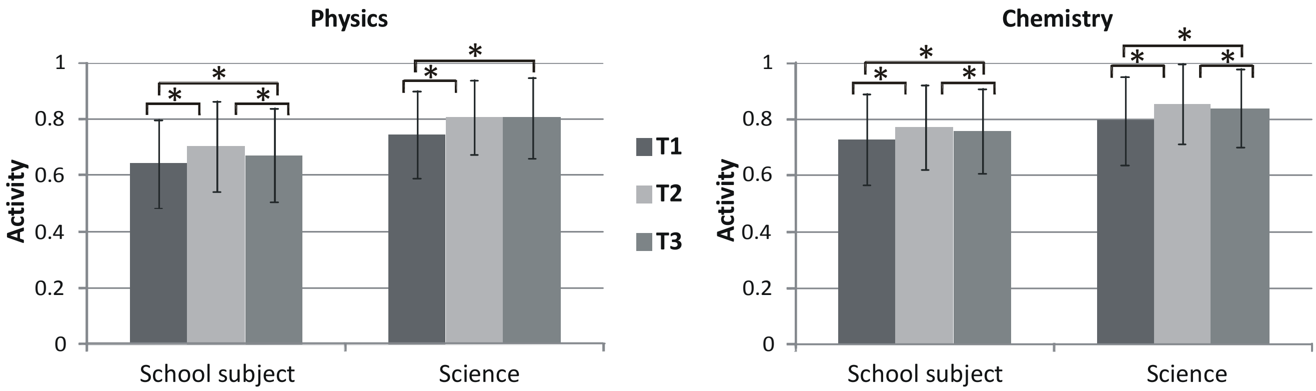

Fig. 1: Development of the image of physics and chemistry as a school subject and as a science

Moreover, both science subjects have a better image than the respective school subjects. The perception of the school subjects is developed and stabilized over many years. Presumably, it is influenced by the prevailing deductive teaching style. Apparently, this largely top-down transmissive and reproductive method conveys an image with a lower activity level. The students clearly differentiate between school and science subjects: the image of the sciences has a more positive connotation; the activity level is higher.

Comparing physics and chemistry, the image of chemistry gets higher scores. This is largely a result of the chemistry focus of the classes. As Baylab plastics is related with chemical industry, mostly chemically oriented teachers opt for visiting the lab with their classes. From this background it is interesting to note that the lab changes the image of physics more deeply than the image of chemistry. This may be due to the fact that the lab involves more physics-related activities (e.g. testing, quality control, technology) than anticipated by the visitors. The effect sizes are small to medium (T1 to T2: d=0.38 for physics as a school subject, d=0.43 for physics as a science, d=0.28 for chemistry as a school subject, d=0.43 for chemistry as a science).
The effects on item level are shown in Fig. 2 and Fig. 3. Especially, for the creative and dynamic related dimensions there is a strong shift of the images towards the positive at the end of the lab visit. For both sciences this effect is for long term. Furthermore, the improved image of physics as science remains stable for more than three months after the lab visit. This refers to the items productive, creative, dynamic, open and innovative. Similarly, the image of chemistry as a science improves significantly. However, a shift backwards to the initial image at T1 is obvious.

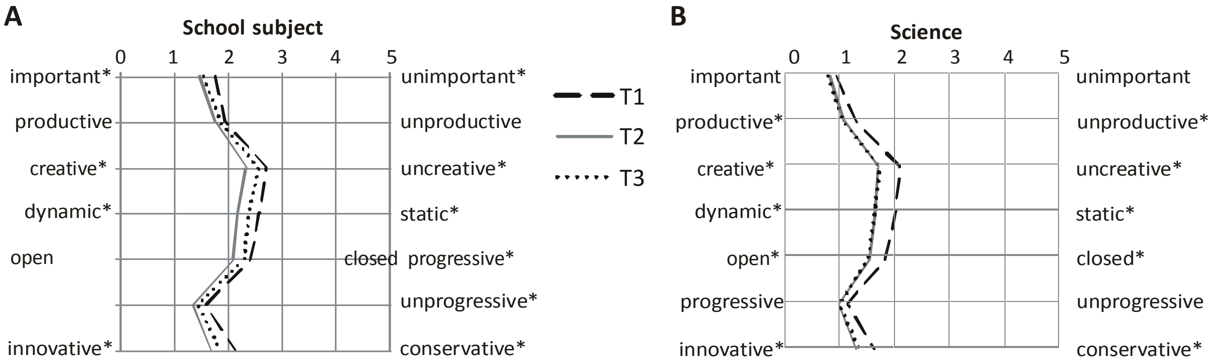

Fig. 2: The image of physics as a school subject (A) and as a science (B), all items individual

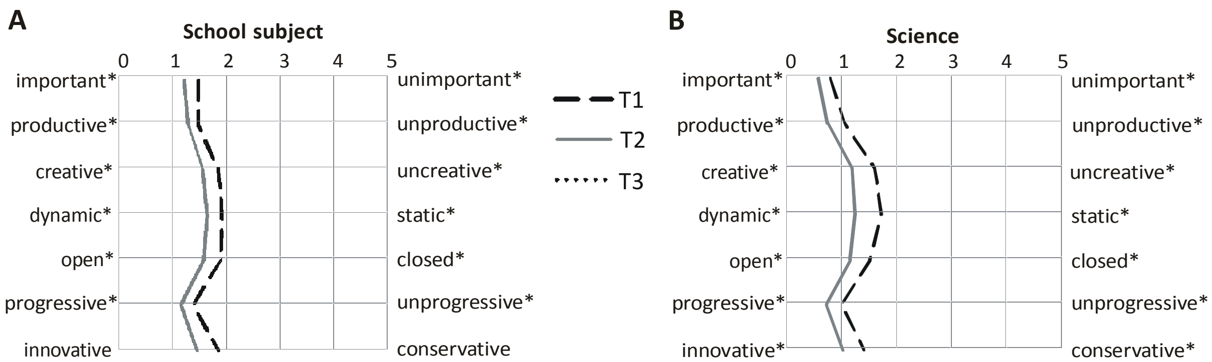

Fig. 3: The image of chemistry as a school subject (A) and as a science (B), all items individual

The results on scale level show more positive scores for the sciences. This can be replicated on item level for every single item. After the intervention the image of the school subjects starts to revert into direction of the first image at T1. Apparently the school subject cannot retain the improved image.

In summary, practical work in an industry context seem to affect the dynamic and creative related aspects of physics and chemistry. After visiting the Baylab plastics the students perceive the hard sciences as a more creative and dynamic field. The lab experience promotes far-reaching and partly sustainable changes of the image.

CONCLUSIONS AND IMPLICATIONS

In addition to existing studies that investigated the development of interest after visiting an out-of-school-laboratory (for example Engeln, 2004; Pawek, 2009), this study investigates ways of changing the image of physics and chemistry both as a school and as a science subject. Baylab plastics fosters an active engagement with science and technology. Practitioners from industry and students are brought together in an authentic science context and learning opportunities complementary to students' school experience are provided. In this context new innovative approaches of experience-based learning in the work place are presented and discussed.

Selected results reveal a positive impact of Baylab plastics on the image of physics and chemistry. This learning laboratory significantly improves the image of physics and chemistry particularly with respect to the creative and dynamic dimensions with a stable long term effect especially for physics. Even single one-day visit at the lab is able to change stereotype views of the hard sciences. The results also reveal differences between the image of the school and science subjects. Apparently the school subjects cannot retain the improved image. Future studies should focus on how to profit from possible image changes in school.

As this very special learning experience in industry facilitates a significant image change it could serve as a model for further interventions. It is desirable that in the near future more activities along similar guiding lines may contribute to increase the attractiveness of professions related to science and technology and may help to reduce the lack of skilled personnel in science and technology related positions.

IMPLEMENTATION OF INQUIRY-BASED LEARNING IN GERMAN SCHOOL PRACTICE

Jens Wilbers[1], Silke Mikelskis-Seifert[1], Katja Maaß[1], Alexander Oettlin[1]
[1]University of Education Freiburg, Germany

Abstract: There are many projects in Europe focusing on changes in methods of teaching mathematics and sciences. One of them is called COMPASS – Common Problem Solving Strategies as Links between Mathematics and Science. In COMPASS new teaching materials are developed and evaluated. Following the COMPASS philosophy, students learn to tackle problems, understand phenomena, find and explain solution strategies solitary as well as in teams. COMPASS is guided by the two central themes of intertwining mathematics and the sciences and paying special attention to socially relevant topics in its teaching modules. COMPASS is a transnational project which is funded by the European Union. The major research interest of the German project team is directed to the constraints and supporting conditions for the implementation of inquiry-based learning strategies in class. This paper introduces to the concept of COMPASS in Germany, and the approach of teachers' professional development applied in the project. It elaborates on the evaluation design and presents first results of the studies.

Keywords: Inquiry based learning · intervention study · teacher professional development · science learning · scientific process skills

BACKGROUND

The professional world places high demands on young people and graduates. Therefore students should not only study mathematics and sciences on a mere content level. It's a both demanding and significant additional learning objective of science and mathematics classes to learn and identify problems, understand phenomena and find solution strategies both solitary, and as members of a team. Students need to be able to quest for and select information, develop solution strategies, and explain them to others. In order to achieve this, a change in teaching and learning behaviours must take place. Our approach of inquiry-based learning is at its heard multidisciplinary. Challenging problems which are authentic from a scientific point of view and relevant to the students' daily lives are the nucleus of closely intertwined teaching modules in various subjects (most of all mathematics and the sciences) that contribute to the problem's solution. Dealing with challenging and relevant topics promotes lifelong learning in a knowledge society. It also fosters the ability to develop skills (e.g. softskills like team work competencies) and to attain and apply knowledge. In general, the main focus of COMPASS is on developing, testing and evaluating teaching materials for inquiry-based learning. Educational and empirical research offers many findings on contemporary and appropriate learning and teaching strategies in mathematics and the sciences. But evidently, a change in learning and teaching behaviour has not taken place (PISA, Rocard-Report, 2007). For this reason COMPASS is focused on the implementation of inquiry-based learning throughout Europe. COMPASS comprises six institutions from six European countries (Germany, Netherlands, Spain, Slovakia, Cyprus, United Kingdom). The project is managed and coordinated from Freiburg. The project was running from November 2009 to October 2011.

RATIONALE

Defining Inquiry Based Learning in terms of the COMPASS project

Educational and empirical research offer a wide range of approaches to inquiry-based learning. So there are many definitions of inquiry-based learning to be found (e.g. Dewey, 1910; Linn, Davis & Bell, 2004). It is therefore important to rely on one definition of inquiry-based learning within COMPASS. The definition, upon which COMPASS has agreed, is: *Inquiry-based learning includes many activities such as observing, asking questions, collecting available information (internet, literature), planning experiments, collecting, analysing and evaluating data, finding answers and explanations, presenting and explaining results. It is essential to formulate hypothesis, and to subsequently think critically and logically about given conditions and alternatives. Inquiry-based learning is based on the fact that students play the active role and learn to formulate their own hypothesis. Formal explanations follow the aforementioned activities.* Merging mathematical and scientific approaches in terms of interdisciplinary working methods is an additional key characteristic of inquiry-based learning. According to this definition COMPASS materials rely on an inquiry-based learning approach.

Implementation of COMPASS materials in Germany

As already outlined the central objective of the project is to evolve the teachers' thinking about teaching and learning mathematics and science as well as to improve the range and quality of their teaching behaviour by developing teaching and learning methods. To develop teachers' ways of thinking about "high quality" teaching practice in the sense of inquiry-based learning, we draw on theoretical and conceptual frameworks that address teacher competencies, such as Shulman's (1987) approach of "content specific pedagogical knowledge" (PCK) or the Model of Educational Reconstruction (Duit et al., 2005) and we refer to results of programs like SINUS or Physics in Contexts (see Ostermeier et al., 2010 or Author, 2010). Furthermore teacher training offers the opportunity for teachers to test and learn how to change school practice by using COMPASS materials in class. Within the scope of the project teachers work closely together with mathematics and science educators. The cooperation between teachers and educators is viewed as "symbiotic". This means that teachers are seen as experts in the field of practice whereas Mathematics and science educators are familiar with recent research literature and innovative instructional methods. The role of the educators is to serve as coaches guiding the work in "communities of practice" made up of teachers and educators. We expect a close cooperation between teachers and educators supporting a successful implementation of COMPASS materials in school practice.

The tripartite school system in Germany poses a great challenge because according to their level of performance students are taught in different types of schools for the low (Hauptschule), average (Realschule) and high achieving students (Gymnasium). Therefore it is required to develop three types of materials according to the various levels of performance. The prevailing conditions can vary greatly from school to school. An analysis of needs conducted in daily school life draws a fairly heterogeneous picture. All three types of schools offer the opportunity for interdisciplinary learning in terms of inquiry-based learning. Especially in the case of schools for the lower and average achieving students (Hauptschule, Realschule) some traditional school subjects were replaced by subject clusters (e.g. subject cluster science). This trend differs from the one that is evident in Gymnasiums. In a survey of 50 teachers, all teachers stated that the contextual framework has a favourable effect on the implementation of COMPASS materials in mathematics and science classes. Nonetheless the teachers did not feel comfortable and prepared to teach while applying such methods. They furthermore claimed that they did not know of any successfully tested and reliable teaching materials. This is where COMPASS applies.

METHODS

Projects like COMPASS require an evaluation. Evaluation research offers quite a number of evaluation standards as well as reliable evaluation models. Stufflebeam (1974) introduced the CIPP model of curriculum evaluation, which includes context evaluation, input evaluation, process evaluation and product evaluation. This framework provides a concrete foundation in situations where decisions have to be made. Our evaluation approach is oriented towards the CIPP model. The following research questions are relevant to the COMPASS project:

1. *Questions concerning the implementation:* How do teachers accept the materials? In which ways do teachers implement the materials in their daily teaching practice? Which supporting and or hindering factors concerning the implementation could be identified?
2. *Questions concerning the teachers:* What are the project-related expectations and interests of teachers, participating in the COMPASS activities? What are their beliefs in the fields of inquiry-based learning and interdisciplinary approaches of teaching and learning? To what extent do they benefit from this project? In which ways do beliefs just as well as instructional practices change during the lifetime of the project and due to the application of COMPASS materials?
3. *Questions concerning students:* To what extent and how do students perceive inquiry-based learning? Do they develop new perceptions of mathematics and sciences? Do students develop adequate competencies in the area of working like a scientist?

A successful evaluation includes formative and summative aspects and employs a mixed-methods-design (qualitative and quantitative analysis). Formative evaluation supports and documents the implementation process at different levels. Summative evaluation investigates the implementation of inquiry-based learning on a European level and potential development of students' and teachers' competencies. The analysis is based on teacher and student data, which were collected in pilot schools.

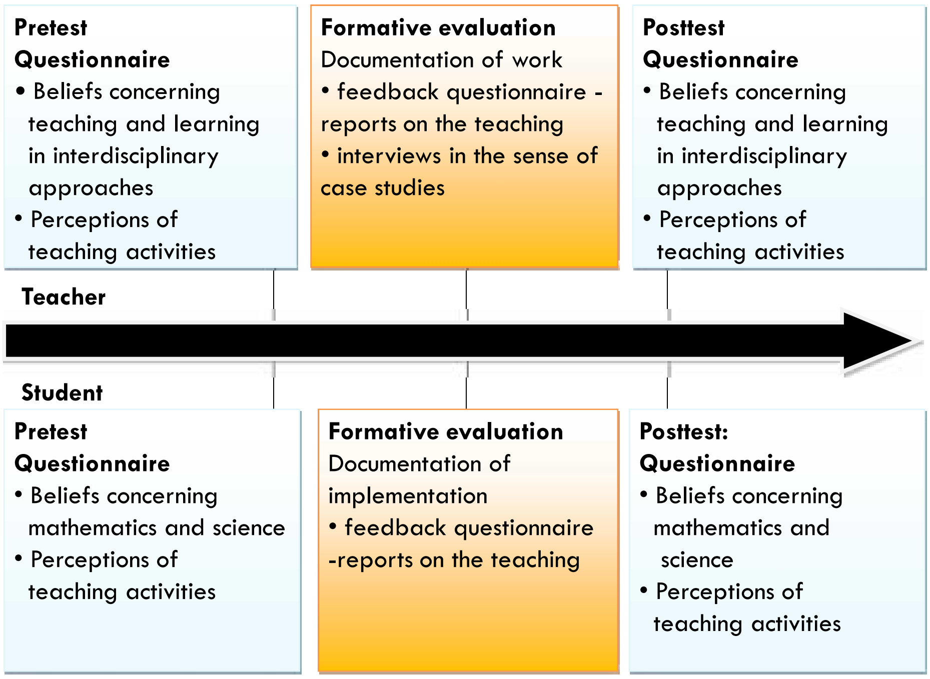

Fig. 1: Design of evaluation

Focus on teachers: On the teachers' side, a questionnaire is administered which aims at various aspects of interdisciplinary teaching and the teachers' related beliefs and self-directed perceptions of instructional practices. The teachers who took part in the survey were asked to fill in the questionnaire at the beginning and the end of testing Compass materials.

In addition, we document the implementation process in the participating countries. We also ask teachers to provide information on their acceptance of the Compass units.

Focus on students: A students' questionnaire was employed at the beginning and at the end of the testing process. The aim was to analyse students' beliefs concerning mathematics and science. In addition we wanted to know whether the perceived teaching practice from the students' perspectives changes from the beginning to the end of the testing process. We used additional questionnaires to have a feedback from the students on the Compass unit.

SELECTED RESULTS

The materials and teaching units were tested by different teachers in every country participating in the COMPASS project. Selected results are presented and discussed in the following.

The COMPASS units are based on the blending of science and mathematics content relating it to everyday contexts which are relevant to the students. Furthermore the COMPASS units take inquiry- and modelling-oriented approaches into account. Relevant societal problems play an important role. Hence, the Compass units aim at fostering the students' ability of critical argumentation.

Our hypotheses for the evaluation study are:

1) The specific characteristics of the COMPASS units have a positive effect on the students' motivation to deal with science and mathematics.
2) Compared to regular teaching practices COMPASS units lead to more open and student centred teaching activities.

Changes in students' beliefs

Expecting changes in students´ attitudes based on the specific characteristics of the COMPASS units we supposed a positive influence on the students' motivation. We were able to develop two adequate motivation scales of high reliability.

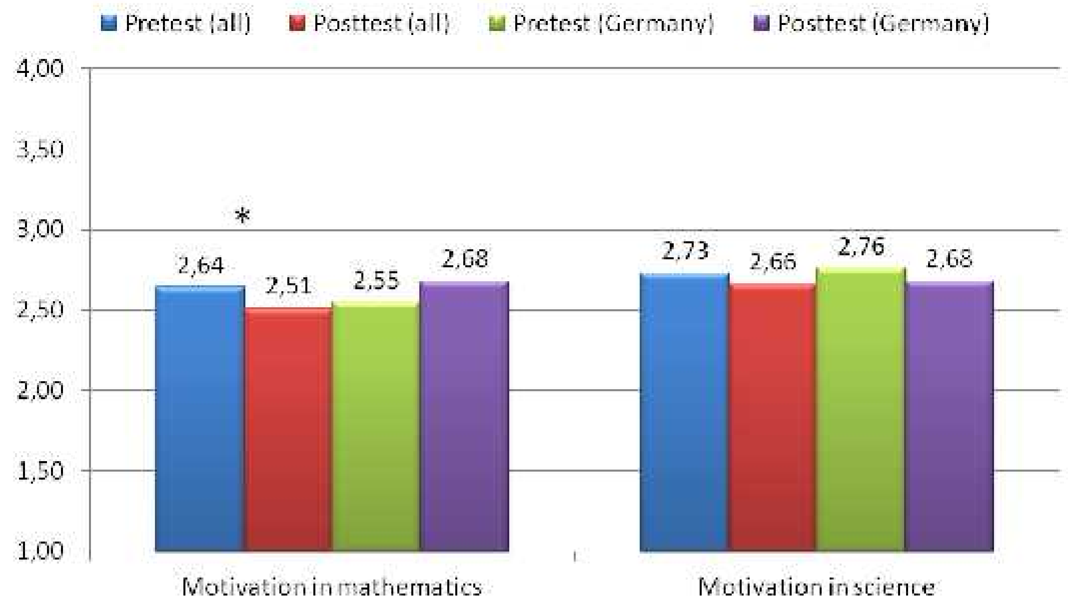

Fig. 2: Students´ motivation

Regarding the whole sample the motivation in mathematics decreases significantly. This is due to the significant decrease regarding the boys, whereas the girls' motivation is stable. In Germany, the mean value of motivation in mathematics does not change significantly between pre- and post-test.

With respect to science the motivation is stable. There is no significant difference between motivation in mathematics and science in pre- and post-test. Furthermore, we were able to develop two adequate scales concerning application oriented views. The reliability of these scales is also very satisfactory.

	Mathematics: application oriented view	Science: application oriented view
Pretest	M=2,95 SD=0,77	M=3,06 SD=0,47
Posttest	M=2,94 SD=0,79	M=3,04 SD=0,47

Fig. 3: Application oriented view in mathematics and science

The results shown in figure 3 indicate that in the field of application oriented views the students` already hold adequate beliefs. Hence there are no significant changes in these beliefs between pre- and post-test. There are neither country specific nor subject specific effects.

Changes in teaching behaviour

To what extend do instructional practices change during the lifetime of the project and due to the application of COMPASS materials? Can we observe differences between mathematics and science?

In the first step, we developed three scales each analysing the teaching practices in both mathematics and science. These scales show satisfactory reliabilities and were used in the teachers´ and students´ questionnaires. The following table presents the results concerning the perceived teaching practices from the students' and the changes from the beginning to the end of the testing process.

	Student-centred methods (in Math)	Discussion culture (in Math)	Application oriented teaching (in Math)
pretest	M=2,59 SD=0,65	M=2,59 SD=0,80	M=2,15 SD=0,66
posttest	M=2,78 SD=0,55	M=2,63 SD=0,79	M=2,35 SD=0,62

Table: Students´ estimation of teaching behaviour (Likert scales, 1 .. disagree and 4 .. agree)

In the scales "student-centred methods in mathematics" and "application oriented teaching in mathematics", there are significant increases in the "paneuropean" sample. Self-responsible learning and student-centred methods are paid substantial attention in the COMPASS units. Here, we find a significant increase over the mean value of this scale. Application oriented teaching also plays an important role in the COMPASS philosophy. The mean value of this scale increases significantly. Same effects can be found regarding the German COMPASS schools.

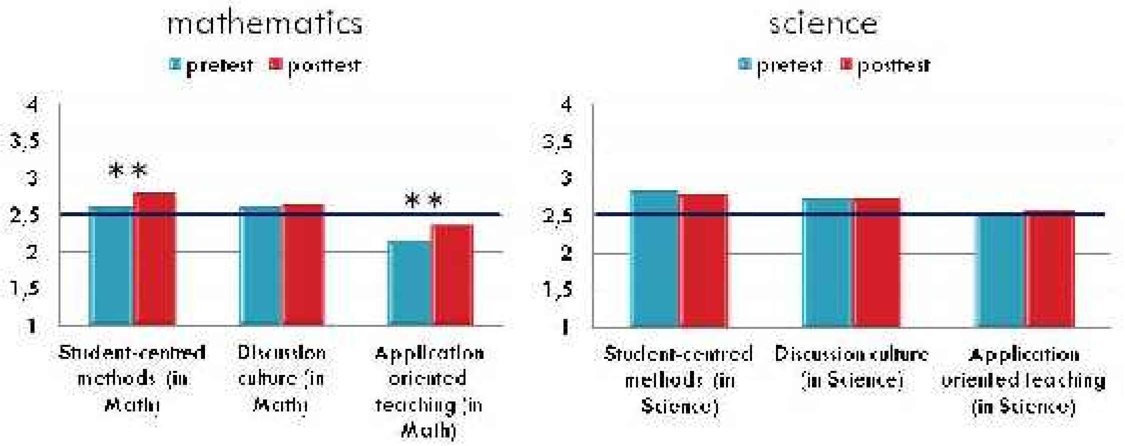

Fig. 4: Students´ estimations on teaching behaviour

As expected, there are significant differences between teaching behaviour in mathematics and teaching behaviour in science. Compared to mathematics in two scales the mean values are on a higher level in science: Teaching practices in science tend to be more student-centred and application oriented as opposed to the teaching in mathematics. On a high level there are no changes in the science scales.

CONCLUSIONS

All in all it can be stated that the COMPASS materials were well received by the participating teachers. Science teachers just as well as mathematics teachers report a significant impact of COMPASS materials on their teaching. The students however tended to perceive significant changes in the teaching practices mainly with respect to their mathematics classes. Hence it is most of all mathematics that benefits as a school subject from the ideas which are inherent to the COMPASS units.

Abstract: Sex is considered to be one of the most significant factors influencing attitudes towards science. However, the so-called brain type approach from cognitive science suggests that the difference in motivation to learn science does not primarily differentiate the girls from the boys, but rather the so-called systemisers from the empathizers. Boys are, on average, more motivated to learn science, not because they are boys but because boys tend to be systemizers, and *vice versa* for girls. Previous research on Swiss students has indeed shown full mediation between sex and motivation to learn science. The present study was conducted in order to confirm this relation in a cross-cultural study. It involved four countries (Malaysia, Slovenia, Switzerland, and Turkey) and 1200 students in upper secondary level. The study used structural equation modelling in order to test the hypothesised relationship. The results confirm the full mediation of systemizing between sex and motivation to learn science. The results are stable and the model fit is excellent. Systemizing explains 27% of the motivation to learn science. The indirect impact of sex on motivation is significant but low. The results are invariant across all four cultures. It is therefore concluded that students' brain type, seen as a basic cognitive personal trait, is more important as a predicator for motivation to learn science than sex. It should be taken into account both in science teaching and research of science education.

Keywords: Gender, Sex, Motivation, Culture, Cognition

INTRODUCTION

A number of studies indicate that boys have a more positive attitude towards science education than girls and this trend is seen most profoundly in studies which do not differentiate between science subjects but rather investigate the general attitude of students toward science lessons (Osborne & Collins, 2003; Sjøberg & Schreiner, 2005).

If, however, studies focus on students' interest and motivation to learn science, the situation becomes less clear. Glynn, Taasoobshirazi, & Brickman (2007), for example, were unable to find a relationship between sex and motivation to learn science among American students with non-science majors. This ambivalence is also salient, when subdimensions of motivation are taken into account. For example Britner's study (2008) found that girls had stronger self-efficacy in science classes, particularly in earth and environmental sciences, while other studies reported a reverse result (cf. Glynn, Taasoobshirazi, & Brickman, 2009).

In this unclear situation, research results from cognitive science, provided by Billington,

Baron-Cohen, & Wheelwright (2007), is of particular interest. These researchers compared natural science and human science students in view of their sex and their so-called brain type. They showed that male sex was indeed a statistical predictor for studying natural science. However, the brain type had a far greater influence on the path of study than sex.
The concept of brain type was originally formed within the field of autism research (Baron-Cohen, 2002). Baron-Cohen and colleagues developed a cognition concept by proposing the interplay of two core psychological dimensions: empathizing (E) and systemizing (S) (Baron-Cohen, Knickmeyer, & Belmonte, 2005). The brain type is defined as the interplay between the two abilities. There exists a score EQ (empathy quotient) and a score SQ (systemizing quotient) to measure the empathizing and the systemizing dimensions respectively. Brain type is basically calculated as a mathematically normalized difference of EQ and SQ.
Based on their results, Billington et al. (2007) suggested that perceptions toward natural science are fundamentally influenced by brain type rather than by sex. Thus, the difference between motivation for learning science does not primarily differentiate the girls from the boys, but rather the systemizers from the empathizers. The difference observed between the sexes results from the tendency for girls to be empathizers and the boys to be systemizers and from the finding that systemizers, in general, are more interested in natural sciences than the empathizers.
This hypothesis has recently been tested by research on Swiss students (Zeyer, 2010; Zeyer, Bölsterli, Brovelli & Odermatt, in press; Zeyer & Wolf, 2010). Structural equation modeling indeed showed full mediation of systemizing (one of the cognitive dimensions of the brain type) between sex and motivation to learn science. This means that sex had no direct impact on motivation to learn science, but only through its impact on systemizing, which itself explained 25% of motivation to learn science. However, results differed from expectations since there was no relation between empathizing (the second cognitive dimension of the brain type) and motivation to learn science.
The interesting and open question remained, were these relations between sex, empathizing and sytemizing, and motivation to learn science were specific for the Swiss science education culture, or were they indeed applicable and constant across other cultures. The present study was conducted in order to investigate this research question in a cross-cultural setting. The study involved four countries (Malaysia, Slovenia, Switzerland, and Turkey) and 1300 students in upper secondary level.
Structural equation modeling was used in this study in order to confirm the hypothesized relationship in the overall sample and in each of the involved cultures.

THEORETICAL BACKGROUND

Brain type

The Brain Type Theory initially emerged from a theoretically and empirically substantiated concept from Baron-Cohen and colleagues (2005). In this theory, two fundamental psychological dimensions are proposed: systemizing and empathizing (Billington et al., 2007). These relate respectively to the “consciousness of a physical world” and to the “consciousness of a mental world” (Baron-Cohen, 1999).
The basic principle of the brain type theory is that each human uses both of the available psychological dimensions systemizing and empathizing. Generally, however, one of the dimensions, systemizing or empathizing, is predominant. A person who is more influenced by systemizing than by empathizing is described as a systemizer. In the reverse case, a person is called an empathizer. People who are equipped equally with both abilities are called balanced. This concept is known as the E-S-Model.

An important result from the research, which arises from using the E-S-model is that women are on average empathizers (that is their normalized Empathizing Quotient is in general larger than the normalized Systematizing Quotient, E > S). Men are on average systemizers (S > E) (Baron-Cohen, 2002). However, this generalization is only applicable on average as there are also systemizers among the women and empathizers among the men.

Motivation to Learn Science

The central focus in motivation research is on the conditions and processes that facilitate the students' persistence, performance and healthy personal development (Ryan and Deci, 2009). In the study presented here, we use Glynn and Koballa's theoretical motivation framework (2006) to ensure comparability with their results. Thus motivation is defined as "… the internal state that arouses, directs, and sustains students' behavior towards achieving certain goals. In studying the motivation to learn science, researchers attempt to explain why students strive for particular goals, how intensively they strive, how long they strive, and what feelings and emotions characterize them in this process" (Glynn & Koballa, 2006, p. 1090). Based on research within the social-cognitive motivational framework (Bandura, 2001), Glen and colleagues identify six important motivational constructs that include intrinsic and extrinsic motivation, relevance to personal goals, self-determination, self-efficacy, and assessment anxiety (Glynn & Koballa, 2006).

The Questionnaire

In part A of our questionnaire, we used the SQ and the EQ questionnaire by Baron-Cohen (2003). Each country translated the questionnaire into its own language. Both the SQ and the EQ questionnaires contain 60-items in forced choice format, comprising 40 cognitive style items and 20 control items. The SQ includes questions such as "If I had a collection (e.g. coins, CDs, stamps), it would be highly organized" and "When I learn a language I become intrigued by grammatical rules". Similarly, the EQ includes items such as "I am good at predicting what someone will do" to measure cognitive empathy or "I usually stay emotionally detached while watching a film" to measure the affective component of empathy.

On both the EQ and the SQ questionnaires, participants are asked to respond on a four-point Likert scale with "definitely agree", "slightly agree", "slightly disagree" or "definitely disagree", and approximately half the items are reverse scored to avoid response bias.

In Part B of the questionnaire, we asked students to respond to the 30 items of the Science Motivation Questionnaire (SMQ; (Glynn & Koballa, 2006)). The items were translated into German. The SMQ items were developed based on the motivation concepts described earlier in this article. Students respond to each of the 30 randomly ordered items on a 5-point Likert type scale ranging from 1 (never) to 5 (always). Anxiety about science assessment items are reverse scored when added to the total, so a higher score on this component means less anxiety.

METHOD AND SAMPLE

A total of 1300 students from four countries, i.e. Malaysia, Slovenia, Switzerland, and Turkey were investigated. After cleaning the raw data, the sample included 1188 students, 476 male students (40.1%) and 712 female students (59.9%). The mean age was m_{age}=16.59 years (SD=.905). The distribution of the students in the different countries is indicated in Table 1.

The students were visited in their classes. For the duration of two lessons, students were required to be fully involved in the research by filling out the questionnaires. They were informed that a study was being conducted to further understand students' motivation to take science classes. Thereafter, the general conditions for the research were presented and finally, the questionnaires were distributed. The students had a break in between filling out each of the questionnaires and then the completed questionnaires were collected. In each class, the same standardized process was adhered to.

Table 1
The structure of the sample by the countries

	Malaysia	Slovenia	Turkey	Switzerland
Male	126	107	119	124
Female	159	218	142	193
Total	285	325	261	317

RESULTS

The procedure of structural modeling

For the simultaneous test of the structural and measurement hypotheses, a causal structure was posited among the concepts of the EQ and the SQ, the SMQ, and sex. The tested structural equation model reflects the hypothesis that engagement in science is influenced by the SQ and by the EQ, and that sex only has an indirect (mimic) effect on the engagement in science through its impact on the two latent variables EQ and SQ. The model is a first order model, that is, the second order construct of brain type has not been introduced in the model.

Item Reduction

In order to be able to include SQ, EQ, and SMQ as single latent variables into the model, each of them had to undergo a substantial item reduction. Given the sample size and the number of SMQ items, 12-15 items at most for the structural model seemed to be adequate (Kim, 2005). Concerning the unidimensional item sets of EQ and SQ, a random assignment method was used (Little, Cunningham, Shahar, & Widaman, 2002). Each item from the EQ resp. the SQ was randomly and without replacement assigned to three parcels. This method is appropriate when items stem from a common pool, as it is the case for questionnaire items like those in the EQ resp. the SQ questionnaire.
A domain-representative approach was used for the SMQ, a multidimensional item set. With this method, parcels are constructed by combining items from different dimensions into item sets. It attempts to account for multidimensionality by creating parcels that encompass not only the common variance, but also the reliable unique facets of the multiple dimensions. Given that each of the six subdomain of the SMQ consists of five items, the domain-representative approach produced five parcels of six items each stemming from the different subdomains.

Model Confirmation

Due to the complexity of the empirical test, a two-step process was employed to confirm the first order model. All the estimates were produced using AMOS 16.0 (Airbuckle, 1997) and the estimation method of maximum-likelihood. As a first step, the measurement models of the EQ, the SQ and the SMQ were tested through confirmatory factor analysis. As discussed in subsection 2.1.3, three random parcels of the SQ items resp. the EQ items and five domain-representative parcels of the SQM items were used to operationalize the three latent variables. In the second step, the full structural model was directly tested. It reflects the core hypothesis of this study that the SQ and also the EQ have an impact on each PISA key concept of engagement in science, and that the impact of sex is only indirect (mimic) via the EQ and the SQ.

The full structural model

After an intensive analysis of the modification indices, significance tests, standard errors, and several intermediate model modifications, the structural equation model in Figure 1 is regarded as the best fit for the data.

The definitive model has undergone important structural modifications. A salient feature is the complete absence of the EQ, the empathizing quotient, in the diagram. This latent variable indeed showed only small and non-significant loadings on all other latent variables in the model. Sex also had no impact on the EQ. Its removal entailed an improved overall fit.

The factor loadings of the remaining measurement instruments are statistically highly significant ($p<.01$) and the corresponding signs concur with the hypotheses. The standardized estimates, from .74 to .89, confirm the formal validity of the individual items (see Bollen, 2002). The explained variances of the items vary between .54 and .79; this is a highly acceptable range of magnitudes. Descriptively, the model works very well which is indicated firstly by a highly acceptable goodness of fit index (GFI) of .982. Secondly, the baseline comparison (CFI) is 0.987. From an inferential point of view, the model is compatible with the data (CMIN/DF=3.876). Finally, RMSEA<.49 and PCLOSE=.530 indicate a very good fit (for the fit measures see Arbuckle, 1997, p. 551ff).

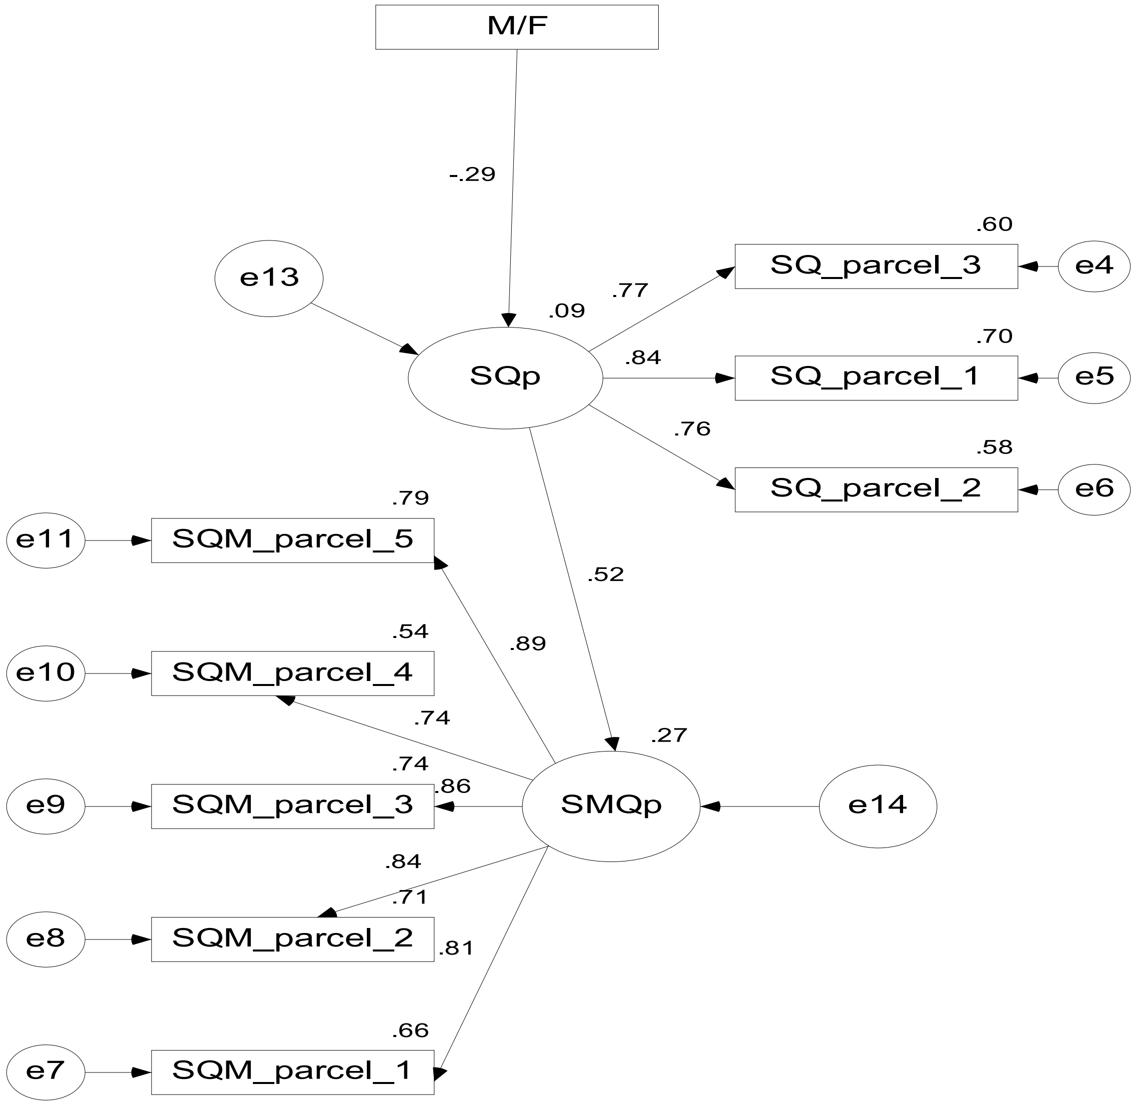
The standardized regression weight of the SQ on the SMQ (.52) is considerably high. Thus, the explanatory power of the model is high. The impact of the SQ can explain 27% of the variation of the SMQ.

There is also a highly significant factor loading of sex on the SQ. The standardized regression weight is negative (-.29) because this variable represents “female” by the value 1, while 0 represents “male.” Therefore, in this model, males have a higher SQ (which aligns with the result in the descriptive part of this study). The impact of sex explains 9% of the variation of the SQ.

Given the good fit, the high amount of multiple square correlations, the high, equally distributed and highly significant factor loadings, this model is considered to be appropriate as a full model for the presented theory. It reflects the theoretical background of the brain type theory. It confirms the hypothesis that motivation to learn science is highly influenced by the systemizing cognition, while the EQ, representing the empathizing cognition, has no significant influence on this motivation. It also confirms the hypothesis that sex indirectly affects the motivation to learn science via the SQ.

The indirect effect of sex was calculated by bootstrapping. The standardized indirect effect of sex on the SMQ (-.152) is highly significant, but very small. Since there is no significant direct loading of sex on the SMQ, the effect of sex on the motivation to learn science is strictly indirect and minimal.

Figure 1
The full structural model. Standardized estimates.



Group comparison between male and female students

In order to compare the results of the different cultures, the method of simultaneous multiple group comparison was used, which allows an examination of the structure of the causal relations in both the measurement and the structural model (see Byrne, 2010). Firstly, a configural model (with no equality constraints imposed) was created by introducing the four data sets of the four different cultures. As expected, it reproduced the goodness of fit results of the basic model (CFI=.993, RMSA=.019, PCLOSE=1). Therefore, the four cultural groups show a comparable model structure, i.e. configural invariance.
Secondly, the metric (measurement) and the scalar invariance (structural) models were created and tested for invariance. The fit of the measurement model was consistent with that of the configural model (CFI=.985; RMSEA = .025). The difference in the comparative fit

ΔCFI=.008 is smaller than .01, which accepts the invariance hypothesis (Cheung & Rensvold, 2002). The model therefore shows metric invariance. The fit of the structural model was also consistent with that of the configural model (CFI=.911; RMSEA = .056). Therefore, the intercepts were released in both SQ and SMQ, for one resp. three indicators. The released model presented a much better fit (CFI=.979, RMSEA=.028), and the CFI difference test now yielded ΔCFI = .006), which accepted the hypothesis of partial scalar invariance. Therefore, it was concluded that the multiple group model displayed partial scalar invariance, which allows for a comparison of factor loadings and latent means between the four groups (Steenkamp & Baumgartner, 1998). Table 2 shows the squared multiple correlations and the implied means of the SMQ, and the means of the SQ for all four cultures.

Table 2.
Cross cultural comparison of the squared multiple correlations (SMC) and the latent means (means)

	SMC SQ	SMC SMQ	mean SQ	mean SMQ
Switzerland	.18	.3	7.27	16.55
Turkey	.03	.47	10.08	16.05
Malaysia	.05	.29	10.22	14.01
Slovenia	.13	.25	8.89	14.62

The difference between the impacts of sex on the SQ across the cultures is not significant. The same holds for the impacts of the SQ on the SMQ. It is the same across all the involved cultures. The difference of the mean SMQ across the cultures is not significant, neither. The only significant difference can be found between the mean SQs. The Swiss mean SQ is the lowest, followed by the mean SQ in Slovenia ($p<.01$). The mean SQs of Turkey and Malaysia are higher, but equal.

DISCUSSION

The Structural Equation Modeling (SEM) part of the results provides a structural model that reflects and confirms the theoretical background of the E-S theory and confirms the results of the previous Swiss studies (Zeyer, 2010; Zeyer, Bölsterli, Brovelli & Odermatt, in press; Zeyer & Wolf, 2010) in a cross-cultural context. As in the Swiss studies, three salient aspects are included in the model: the impact of the SQ on the engagement in science, the absence of an impact of the EQ on the engagement in science, and the strictly indirect influence of sex on E-S. These features are remarkably the same in all four cultures. The only significant difference can be found in the means of the SQ, which is lowest among Swiss students.
The impact of the SQ on motivation to learn science is fairly large. The more somebody systemizes, the greater their motivation to learn science will be. Secondly, the structural model suggests that the EQ does not influence the engagement in science. Empathizing is defined as a drive to identify another person's mental state and to respond to a mental state with one from a range of appropriate emotions. Significantly, the personal disposition to empathize seems to have no influence on a person's motivation to learn science. This partially corrects the hypothesis suggested in the work of Billington et al. (2007). If brain type were to influence a person's motivation to learn science, then not only the SQ but also the EQ would be involved. Since brain type is essentially calculated as the difference between the SQ and the EQ, a positive effect of the brain type on the motivation to learn science would imply a negative effect of the EQ on these constructs. Such a negative effect could indeed be motivated

from a theoretical point of view. If empathizing is the drive to deal with mental states, it could well be that a strong interest in mental things could simultaneously diminish engagement in science, at least with science that is explicitly dedicated to physical things.
However, in the structural model presented in this article, this is not the case. Instead, motivation to learn science is independent of a person's drive to empathize. A strong empathizer can be poorly engaged in science; however, their engagement can also be strong. It depends on their SQ. The inverse holds true, i.e. for a low empathizer. This can be interpreted in two different ways. Firstly, one could argue (based on the aforementioned reflections) that general science simply has no link to empathizing at all and therefore, it does not affect the empathizing cognition of a person whatsoever. Another point of view could be that the empathizing dimension of students is not affected because of the particular way general science is taught in the investigated schools (or at least it has no negative impact as suggested by previous research, which could also be taken as a positive point). From the presented data, it is not possible to determine which interpretation is correct.
The third salient feature of our model is that sex only has an indirect (mimic) effect on the motivation to learn science. This is in fact the core hypothesis derived from the findings of Billington et al. (2007) and it is the main motivation for the investigations presented in this paper. The argument follows: engagement in science depends primarily on the SQ of a person. If the systemizing cognition of a student is strong, then they will show a high engagement in science independent of their sex. Since men tend to be stronger systemizers than women, men are prone to be more engaged in science. However, if a man is a weak systemizer, he will not be engaged in science despite his sex. On average, men are more motivated to study science than women, because they are, on average, stronger systemizers. In terms of empathizing, the same holds true for women who are more likely to be less systemizing.

CONCLUSIONS

Overall, the present structural equation model suggests a clear situation. The motivation to learn science is directly and fairly strongly influenced by the SQ and indirectly and very weakly influenced by sex. The study confirms the Swiss results and shows a remarkable stability across four different cultures. Indeed, studies by Wakabayashi, Baron-Cohen, Uchiyama, Yoshida and Wheelwright (2007) have already shown a cross-cultural stability of the E-S theory which fits satisfactorily into their biological framework. Empathizing and systemizing are, according to Baron-Cohen, not cognitive styles but biological abilities. This could explain the stability of our results across the cultures.
Generally, more research must be done to be able to reliably link our findings to the situation in the real science classroom. The challenge for school science seems to be determining how to teach low SQ students, whether they are good empathizers or not. It would be an interesting area of research to investigate how these two groups differ, and how they should be approached to improve the systemizing dimension of their cognitive style, i.e. their drive and ability to analyze the rules underlying a system in order to predict its behavior. The findings suggest that successfully improving the systemizing dimension of these students' cognitive style could consequently lead to improvements in their engagement in science. Research must show if and the extent to which the initial level of systemizing can be improved and how this might be achieved. Although cognition is biologically rooted, it does not mean that it must remain stable over time and inert to education. A second area of inquiry that remains seemingly uninvestigated is if the hypothesis holds true that science lessons do not affect the empathizing cognition of students.

TEACHING AND LEARNING SCIENCE

INVESTIGATING CLASSROOM ACTIVITIES: WHAT KIND OF INFORMATION DO WE GET – AND WHAT DO WE MISS?

Claudia von Aufschnaiter[1]
[1]Justus-Liebig-University Gießen

Abstract: Investigating classroom activities has become one major focus of science education research. It aims to describe patterns of instruction and teacher behavior and relates these descriptions to students' learning progress and students' interests in the subject. Also, such kind of research has become more prominent for investigating teacher profession. However, it has to be noted, that the majority of the projects focus on instruction whereas students' participation and meaning making while being exposed to this instruction is only rarely analyzed (in detail). Research reported draws on a single lesson about force in a grade 8 physics class. The lesson is used as an example to describe how patterns of instruction can be investigated and what kind of measures for instructional quality can be used (and why). The paper will also make an argument for a student focus while investigating instruction.

Keywords: Learning processes, video, classroom activities, instruction, physics

FRAMEWORK AND RESEARCH AIMS

Investigations of classroom activities serve at least two different purposes: They aim at analyzing instruction and its quality in order to gain information on how teaching is conducted and how specific patterns are related to student outcomes and their interest in a subject (e.g., Seidel & Prenzel, 2006). From these studies, research seeks information on "good" teaching. Also, analyses of classroom activities aim to identify teacher profession and how this profession relates to teacher self-reports on what they believe and do (e.g., Widodo, 2004). Results indicate that clear, structured and activating teaching has positive effects on student learning outcomes (e.g., Scheerens, 2008). However, it has to be noted that variables such as "clear" and "activating" are currently typically judged by an observer (based on a coding manual) without taking into account the students' reactions. When is a particular question "clear", "structured" and activating for students who are exposed to this question? Is a "clear" question "clear" to everyone in the class or just to a minority? In order to relate instruction to students' activities and their situated meaning making, the study reported in this paper utilizes criteria to describe instruction which has shown to be useful to describe students' learning processes. The study seeks to explore whether and how these criteria can be used to investigate teaching processes. Furthermore, it is explored how students respond to the instruction by using the same criteria in order to identify opportunities for student learning.

DATA AND METHODS

Data were obtained from physics lessons in Germany. In total, 13 teachers of grade 7 or 8 classes (students aged 13-14 years) participated. The first three lessons about either electric circuits or force were documented on video. In addition, the students completed questionnaires on their interests at the beginning and end of the school year as well as questionnaires on their experiences of single lessons. Pre and post measurements on students' achievements and in depths interviews with every teacher who participated were also conducted. For this paper, two teachers (teacher TB and teacher TS) were chosen who teach force in order to demonstrate methods of analyses used. These two teachers were also chosen because student data differed largely. For teacher TB student interest has not decreased much during a whole year (which is better than for all other teachers) but student do not show large learning gains. For teacher TS, the opposite occurred.

Data is investigated in several steps:

(1) Surface level coding of classroom activities (who is talking, teacher-centered vs. student-centered methods, experiment vs. theory, writing, reading, and so on, categories similar to those documented in e.g., Seidel & Prenzel, 2006). Examples of values with corresponding codes are given in Figure 1.

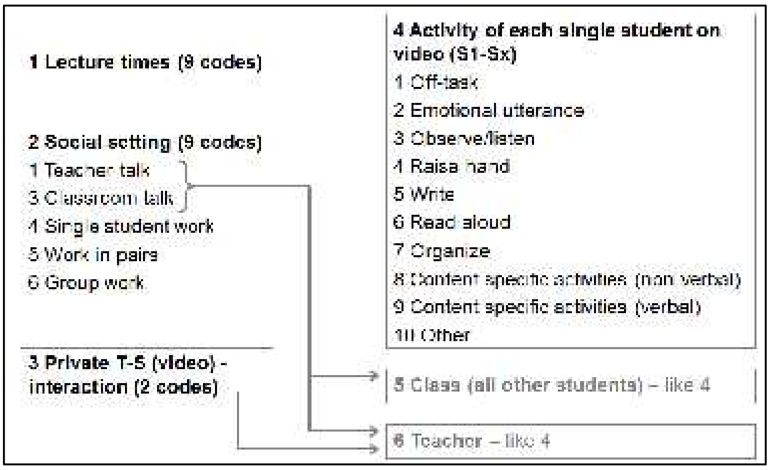

Figure 1. Codes for surface-level analysis of classroom activities. Some codes are coded only if other codes were applied (arrows). Each student on video is coded individually.

(2) Data is transcribed utterance by utterance including all activities relevant for the context such as writing or making use of experimental equipment but leaving out, for instance, activities needed to regulate the balance while sitting on a chair. In order to save time, sometimes those sequences are not transcribed in which only organizational activities (for instance, collecting or distributing experimental material) take place.

(3) Referring to a second order perspective (e.g., Marton & Booth, 1997) individual meaning is constructed from teachers' and students' utterances and activities. A "second order perspective" encompasses the idea that an observer tries to place him- or herself into the other's view to see the world through his or her eyes. This idea concurs with a constructivist notion as it emphasizes that we never really know the others' meanings but try to infer those from participants' activities. Even though we treat our constructions of teachers' and students' meaning as these were "true", we always have to keep in mind that they are only our construction of the others' constructions.

(4) Successive meanings which seem to develop a single idea are condensed to a "line of thought" (see example in Table 1). Those lines of thoughts are used as the basic unit for further analyses.

(5) Main categories for further analyses of lines of thoughts (see also: von Aufschnaiter, 2006; von Aufschnaiter & von Aufschnaiter, 2003; von Aufschnaiter & Rogge, 2010) are

Content: To get an overview about the content specific structure of lessons, content is investigated at different levels: Lines of thoughts are analyzed, sequences referring to the same area of content are identified, and sections comprising a specific topic of the lesson are counted (some results in Table 2). Also, the number of different content elements integrated into one line of thought can be investigated in order to gain information on content "width" of teacher and student talk.

Levels of abstraction or conceptual qualities: Lines of thoughts are assigned to different levels of abstraction (concrete, abstract-static, abstract-dynamic, e.g., von Aufschnaiter, 2006) or to different conceptual qualities (level I: explorative, level II: intuitive rule-based, level III: explicit rule-based with sub-level a) phenomenon-based concepts and sub-level b) model-based concepts, e.g. von Aufschnaiter & Rogge, 2010) in order to assess whether ideas are clearly based on conceptual understanding or seem to refer more to specific experiences indicating a limited understanding. Also, it is assessed whether the ideas are correct or incorrect.

Time: The duration of lines of thoughts, sequences, and sections can be measured in order to investigate the "speed" with which ideas are presented, answers are developed, contents change and so on.

Table 1
Time, transcript and line of thought

Time	Transcript	Line of thought
20 sec	T: O.k. Now we're talking about breakfast. Today, about one hour ago, some of you had breakfast to survive the day. You have to do it. Otherwise, something would be missing. What do you eat then, besides rolls and jam? Why do you it that?	Why do you have to eat rolls and jam for breakfast?

Depending on specific research questions, other codes can be applied to the data, too (for instance, describing student or teacher motivation), however, this will not be discussed in this paper.

RESULTS

A first impression of the videos indicates that the differences between the two teachers at a surface level are rather small: They both collect expressions with "force" in it and they distinguish between physics and non-physics forces. Their main lesson goal is the idea that forces change movement or shape. In order to reach this goal, some experiments, mainly demonstrations, are carried out in both classes.

During their lessons, both teachers were confronted with the distinction between force and energy. Whereas TB initiates the classroom discourse on the distinction himself, TS responds to a question a student has. Figure 2 shows all lines of thoughts TB (bold) and his students develop on this issue. Coherent lines of thoughts are condensed into sequences (horizontal line and duration for each sequence added). These sequences together form one section which is about "energy". For TS, the few coherent lines of thought on energy are part of the section "properties of physics forces". When responding to a student idea that the solar force is energy he uses less than TB the conceptual level IIIb which has shown to be difficult for students (e.g., von Aufschnaiter & Rogge, 2010). Also, at the end of the sequence (Figure 3), he creates a cross-reference to the main idea of the lesson "Forces can make objects move or change their shape."

Is energy the same as force		**IIIb**
Both words can be used for the same thing	45 sec	II/IIIa
Power plants generate [what we call] energy		IIIa
Why do you have to eat rolls and jam for breakfast	20 sec	**II/IIIb**
Why do we have to eat anyway	20 sec	**IIIb**
We have to eat in order to be able to do something		IIIa
Why does a patient need food	15 sec	**IIIb**
He needs energy for his power of resistance		II/IIIa
What does the body do with the energy while sleeping		**IIIb**
We say energy is consumed/dissembled	15 sec	II/IIIa
Energy is needed for the circulatory system		II/IIIa
How is energy consumed		**IIIb**
Somehow sugar emerges	15 sec	II
The patient has to breathe		I/II
All humans are crossbreeds	5 sec	**IIIa**
What we take in is energy	55 sec	**IIIb**
Taking in energy does not give force		**IIIb**
If we do something, we get rid of the energy		**IIIa/IIIb**
Everybody knows that we loose power while making sports		**II/IIIa**
What is lacking then: force or energy		**IIIb**
What does match better		**II/IIIb**
We don't have energy any more		I/II
Energy is the ability to do something, force emerges if one is doing it	15 sec	**IIIb**

Figure 2. TB's section on energy. All lines of thought, for both, teacher (bold) and students are presented as well as the assigned levels for conceptual qualities. Two levels are given whenever the assignment is not clear from what the person says or does. Horizontal lines indicate coherent lines of thoughts, a "sequence", and how long the sequence takes.

Is solar force energy [word association]	II
[...]	
Does solar force belong to physics forces	**II/IIIa**
..?..	
I agree, the solar force comes from the sun	**II**
Where do we have to assign it	**II**
Solar force has to do with current [word association]	II
Current circulates	**IIIb**
This belongs to movement	**IIIa**
Forces can make objects move or change their shape	**IIIa**

Figure 3. TS' sequence on energy. All lines of thought, for both, teacher (bold) and students are presented as well as the assigned levels for conceptual qualities. Two levels are given whenever the assignment is not clear from what the person says or does. The whole duration is 40 seconds.

The analyses of TB's and TS' lesson reveal differences between the two teachers which are summarized in Table 2. TB's lesson seems to be more "dense" as it establishes more lines of thought, refers to more different content elements and uses more sequences all of which with shorter duration. Furthermore, the more general topics of the lesson (described with sections) change more quickly than for TS. From the knowledge we have about student learning (e.g., von Aufschnaiter & Rogge, 2010) the analyses clearly demonstrate that TB's ideas were more often too abstract, presented too fast and included too many different contents and not enough repetition in order to establish specific concepts. Therefore, we may be able to explain why TS' class seems to learn more than TB's class. However, why in both classes interests decrease, and this much more in TS' class, cannot be concluded from the data.

Table 2

Summary of distribution of content over TB's and TS' lessons (sequence: coherent lines of thought; Sections: coherent sequences)

Activity	**TB**	**TS**
Total time of teaching activity (values rounded)	44:30 minutes	46:30 minutes
Number of the teacher's lines of thought	159	98
Approximate number of different content elements developed	27	16
Number of sequences developed	70	34
Mean duration of sequences (values rounded)	40 seconds	80 seconds
Number of sections developed	8	6
Mean duration of sections (values rounded)	5:30 minutes	7:50 minutes

CONCLUSIONS

Current research on classroom activities typically reveals teaching patterns and relates those to student outcomes in order to identify those patterns that seem to be more effective than others. Also, it helps to identify teacher profession. This is the kind of information we currently get from video-based classroom research. However, criteria derived from such kind of research about good instruction are often vague and only loosely related to students' learning pathways. What exactly makes an instruction "clear", "structured" or "activating"? This is the kind of information that typically misses in research on classroom activities. Thus, this paper claims that we need to develop (from research on students' learning processes) criteria which can be used for both a description of teacher *and* student activities in order to relate these together. This information would help to understand better, which kind of instruction is successful (and when) during students' learning processes. This is a different perspective than, much more globally, investigating effectiveness of whole teaching units. There, it is not possible to determine exactly what has caused the "effectiveness". Especially, those measures often lack a focus on *content* (such as the complexity of an explanation which is probably very important for students' understanding). In order to include students' activities in more detail into classroom-based research, classroom videos need to focus not only on the teacher but also on how students respond to instruction. However, it is not likely that all students can be traced in detail. From our research, I would recommend to investigate two to three groups with two to four students each (more information in v. Aufschnaiter & Rogge, 2010). These students can either be chosen randomly or by specific pre-test results (for instance, one group with high and one with low prior knowledge and/or interest).

LEARNING ABOUT GREENHOUSE EFFECT: FRAMING THERMAL PHENOMENA AND OPTICS IN A CHALLENGING CONTEXT

Ugo Besson[1], Anna De Ambrosis, Pasquale Onorato[1]

[1]Department of Physics ”A. Volta”, University of Pavia - Italy

Abstract: We developed a cycle of design, implementation, evaluation and redesign of a teaching learning sequence on the thermal effects of interaction between radiation and matter, infrared emission of bodies, greenhouse effect and global warming. Six high school classes (for a total of 121 students) have been involved in the experimentation of the sequence. The first implementation showed how the introduction of a complex issue requires a progressive conceptual construction and led us to point out a sequence of five cognitive steps necessary to attain a coherent explanation of the greenhouse effect. The accomplishment of these steps entails re-structuring the teaching of thermal phenomena and optics, and discussing the energy balances in stationary conditions of a system exposed to a constant source of energy.

The obtained successes and failures and the analysis of the students' learning progression provided relevant information for challenging the persistent obstacles and misunderstandings. This led to a new cycle of design and implementation of the sequence, involving: the introduction of some activities concerning the teaching of basic energy concepts and thermal phenomena; the production of materials for students aimed at helping them both in classroom activities and in a deeper reflection on the topic; the elaboration of a teacher guide explicating the criteria of the proposed path. The experience confirms the usefulness of significant driving issues as centres of interest promoting the learning of scientific concepts and models, and the need of an iterative cycle of design and implementation of the teaching learning paths in order to take into account effects and elements that only a contextualised practice can reveal.

1. Background, Framework, and Purpose

Our research concerns a cycle of design, implementation, evaluation and redesign of a teaching learning sequence on the thermal effects of interaction between radiation and matter, infrared emission of bodies, greenhouse effect and global warming. This work started in the framework of a European Comenius project aimed to construct a teaching learning sequence focussing on a socially relevant driving issue, the anomalous greenhouse effect and global warming, and continued within a Project funded by the Regional Office of the Italian Ministry of Education aimed at introducing innovative contents and methods in the High School Physics curriculum, which involved six experienced high school teachers. The design of the sequence (described in Besson et al. 2010a) was based on our “three-dimensional approach”, involving a synergic integration of a critical analysis of the scientific content in view of its reconstruction for teaching, an overview of current proposals (textbooks, common teaching), and an analysis of didactic research on the topic (Besson et al. 2010b). The implementation of the sequence in different high school classes and in university courses showed how the introduction of a complex issue in the curriculum makes it evident the necessity of revising the traditional ways of teaching the connected basic subjects (in our case thermal phenomena and optics) and requires a progressive conceptual construction taking into account specific students' needs. Based on these results, we started a new phase of our research aimed to:

- analyse the students' learning process, their cognitive paths, acquisitions and obstacles during the sequence and retained knowledge after the sequence;
- restructure the didactical organisation of the contents and prepare new materials for students in order to overcome the problems evidenced during the previous experimentation.

2. Students' conceptions on the topic

Few researches have been carried out about students' ideas on thermal effects of radiation and the existing ones are focalised on particular aspects:

- effects of radioactivity on living organisms (Rego & Peralta 2006, Lijnse et al 1990, Millar 1994);
- interaction between radiation and metals involving quantum atomic models (Redfors 2001).
- the greenhouse effect and global warming (Boyes et al 1993, Rye et al 1997, Groves & Pugh 1999, Koulaidis & Christidou 1999, Anderson & Wallin 2000, Österlind 2005, Lester et al 2006, Kilinç et al 2008).

It was found, for example, that many students consider:

- the ozone layer depletion and radioactivity as causes of global warming and the skin cancer as an effect;
- the idea of 'trapping' of sun rays by the atmosphere as explanation of the greenhouse effect.

Some researchers also developed ideas and approaches for dealing with these misconceptions on greenhouse effect and global warming (Meadows and Wiesenmayer 1999, Österlind 2005, Lester et al. 2006), but specific studies on student conceptions and teaching proposals for secondary school about radiation-matter interaction are still lacking. In our research we focused on some aspects of the problem (Besson et al. 2010a). For example, we have found:

- a tendency to give absolute meaning to optical properties (transparency, absorptivity, emissivity) as intrinsic characteristics of bodies or materials;
- a lacking or incorrect consideration of infrared emission in thermal balances;
- a confusion between transitory phases and steady state situations;
- a difficulty in considering the interrelation of multiple factors and phenomena implied in energy balances.

3. Rationale

The experimentation of the teaching learning sequence with small groups of students (both in university and in high school) led us to specify a sequence of cognitive steps toward the construction of a coherent explanation of the greenhouse effect:

a) to recognize and explain a stationary condition of temperature for objects exposed to sun or lamp radiation;
b) to differentiate heat and radiation and realize that objects emit thermal radiation;
c) to differentiate visible and infrared radiation and the behaviour of a material for visible and far infrared (glass is transparent to visible but absorbs IR thermal radiation);
d) to put together the knowledge acquired in order to understand the radiative greenhouse effect in a box-model;
e) to understand the greenhouse effect on the Earth and global warming.

In the following we summarize the main features and the contents of the teaching sequence.

a) *To recognize a stationary condition of temperature for objects exposed to sun…*

The thermal effects occurring in an object exposed to solar radiation are studied by means of outdoor experiences. Small metal cylinders of equal masses having white, black and polished surfaces and a transparent cylinder are exposed to solar or lamp light. A temperature sensor is inserted in a little hole in each cylinder; while another sensor measures the ambient temperature. Graphs of temperature versus time for each cylinder are obtained with hand-held data loggers showing the process towards the stationary temperature condition.

b) *To differentiate heat and radiation and recognize that objects emit thermal radiation*
By means of an infrared (IR) radiometer students verify if a body, at a given temperature, emits radiation. The power of the IR radiation emitted by bodies at different temperatures is measured (temperatures under the ambient temperature are also considered). A rapid increase of the emitted radiation power with the temperature is verified. The objects included stones, tree trunks, metals, grass and leaves; some of them should be in the sun and others in shade. Measurements are repeated after having inserted a layer of 'clear' glass or plastic between the objects and the radiation sensor. One observes that the intensity measured by the sensor drastically decreases. This shows that most of the radiation emitted by the considered objects does not pass through the glass (plastic). Then, the word *clear*, used in everyday language for glass and plastic, refers only to visible light.

c) *To differentiate visible and infrared radiation and the behaviour of a material…*
Laboratory activities are performed and discussed with the students to point out that:
– the emission spectrum of a source depends on the temperature (at temperature near to room temperature the emitted radiation is in the far-infrared region);
– optical properties of materials depend on the considered region of the spectrum (on the frequency or wavelength of the radiation);
– some materials are transparent to visible light but absorb far-infrared radiation.
Aiming at *seeing the invisible*, simple observations are performed using a digital camera having infrared sensibility. The spectrum of the lamp of an overhead projector is produced on a white wall by using a transparent prism and students can observe through the camera the presence of IR radiation beyond the red colour. Moreover, the IR radiation emitted by a remote control can be photographed to show that radiation is emitted, and the black 'opaque' plastic that covers the remote control is transparent to this radiation while it is opaque to visible radiation (figure 1).

Fig. 1. "Seeing" through a camera IR radiation emitted by a remote control

d) *The radiative greenhouse effect in a box-model*
The behaviour of a small greenhouse under solar radiation is studied in an outdoor activity. A black aluminium plate is placed at the bottom of a plastic box and it is exposed to solar radiation. The temperature of the plate is measured by means of a temperature sensor until the temperature becomes stationary. Then the box is placed in the shadow and the temperature in the cooling phase is measured.

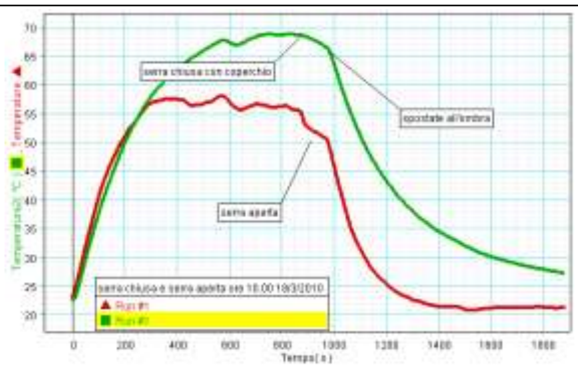

Fig. 2. Examples of temperature versus time graph for the metal plate in the box without and with the lid on.

The same measurements are repeated with a clear glass (or plastic) lid on the top of the box (in this way a small *greenhouse* is created). Before carrying out the experiments, the students are asked to predict and to draw graphs of the temperature of the plate versus time in the two cases. In figure 2 examples of experimental graphs are shown:
An interpretation of the experimental results is discussed with the students by using a model of the energy fluxes (in and out) according to the scheme shown in figure 3.

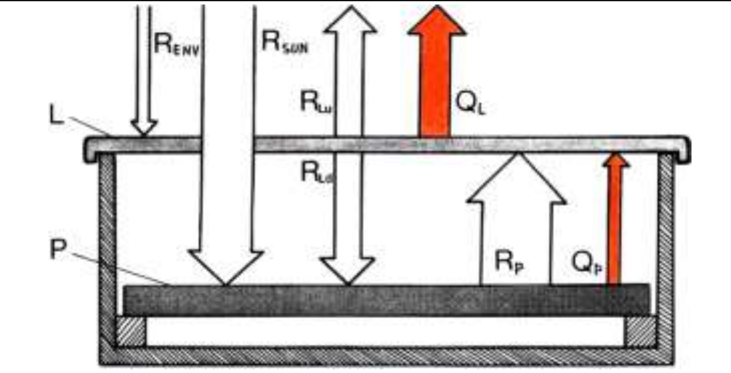

Fig. 3 Radiation and heat fluxes in a small greenhouse box.

e) *To understand the greenhouse effect on the Earth and the global warming*
The model of energy fluxes developed for the greenhouse box can be the starting point to understand the physical aspects of the Earth greenhouse effect. The planet's surface plays the same role as the black plate; the atmosphere plays the role of the glass lid: it is transparent to most of the solar radiation, but absorbs most of the far-infrared radiation emitted by the Earth's surface. This absorption is due primarily to water vapour, clouds and CO_2, with a smaller 5% contribution from the gases O_3, N_2O and CH_4 and a minor contribution of other anthropogenic gases, such as the chlorofluorocarbons. Infrared radiation is emitted by these gases and by air towards the Earth and towards outer space. This dynamics produces a stationary temperature on the surface of the Earth compatible with life. However, an increase of the green house gases concentration makes the energy budget of the system Hearth-atmosphere vary, and as a consequence produces a re-adjustment of the equilibrium temperature in order to restore the energy balance.

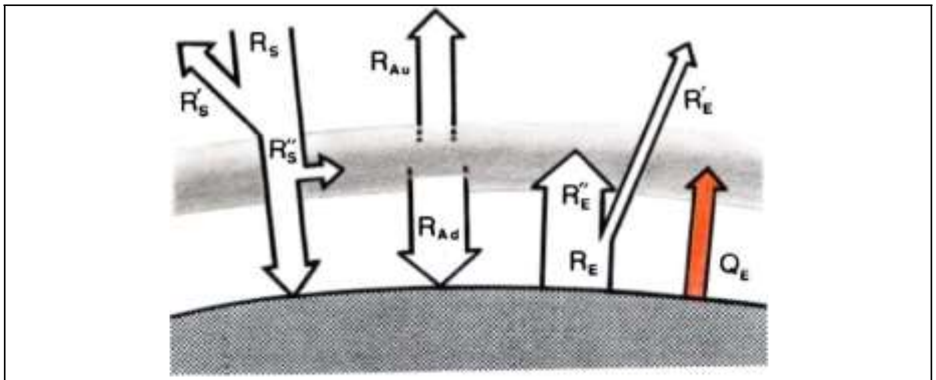

Fig. 4. Modelling radiation and heat fluxes in the *Earth–atmosphere* system

4. Organization of the work and data collection

Six high school classes experimented the sequence, four with 17-18 years old students (group A) and two with 15-16 years old students (group B), for a total of 121 students. Data collection was carried out by means of different tools: an initial and a final questionnaire; work sheets filled in by the students during the experimental activity; video and audio taping of the class activities; teachers' reports on the class work collected in log books. All documents have been discussed in periodical meetings and uploaded in a web site devoted to the project. Teachers prepared a final report where they described which elements of the proposed sequence they considered essential, how they passed from the research plan to their individual teaching plan and to the actual activity in classroom, and the results they observed at the end of the sequence. After having taught the sequence, the teachers continued to work with us to restructure the teaching of thermal phenomena in their classes, to elaborate new materials for students and to prepare new teaching plans for the modified sequence.

5. Results of the first implementation of the sequence

The analysis of the pre- and post- tests has shown clearly an increase in the consideration of the role of radiation in thermal processes (74% vs. 17%), in the awareness of the existence of a stationary temperature (100% vs. 67%) and of the related energy balance (44% vs. 10%,). Nevertheless, this last result is not satisfactory. In fact, the idea of 'saturation' strongly persists (50% vs. 57%): according to this idea materials have their own maximum possible temperature that once it is reached necessarily cannot increase yet. This fact can be interpreted as due to the slowness of the process needed to pass from explanations in terms of object properties to reasoning in terms of interactions and balances.
Concerning the greenhouse effect, data show a strong decrease of explanations based only on thermal isolation (11% vs. 39%) and an increase of correct reasoning (19% vs. 9%, and 26% vs. 12% for group A only) or almost correct, i.e. at least differentiating phenomena of absorption and emission of visible and infrared radiation (18% vs. 4%, and 29% vs. 5% for group A). Nevertheless, the idea of 'trapping' of sun rays strongly persists (43%, and 32% for group A), and the dependence of transmission and absorption on the region of the spectrum is evoked only by 32% of all students and by 45% of group A, vs. 10% and 15% respectively in the pre-test. For comparison, we found that among 51 graduated student teachers only 6% give a correct explanation, 35% express the idea of trapping of sun rays and 31% sustain that sun radiation enters and heats but heat cannot get out or can get out partially by conduction and convection.

6. A new cycle of design and implementation

These results, good but not optimal, confirmed the difficulty of the topic and suggested some improvements of the sequence. Teachers observed that some students' difficulties could be caused by an incorrect or insufficient understanding of basic topics concerning energy concepts and thermal phenomena. Students' reasoning is strongly influenced by the first presentation of the topic (examples, descriptions, explanations...) since they tend to reuse the same initial patterns of reasoning, even if not appropriate, for the new situation. We call this tendency, observed also in other topics, the "imprinting" phenomenon in science learning (resuming the term introduced by K. Lorenz). To avoid this negative effect, it is useful to present since the beginning a wide panorama of different situations and factors, in a qualitative and simplified manner, in order to make it easier for students form an idea not limited on a particular case or aspect. For example, in introducing thermal phenomena it is better to present from the onset many different ways for changing the temperature of a body and also consider stationary situations without thermal equilibrium (in usual simple cases such as a room where the heating is on but the temperature is constant).To interpret stationary conditions, drawings, schemata and data representing energy fluxes can be used.
Based on these results, we started a new phase of research aimed to:

- Revise some aspects of the sequence, particularly the way of teaching basic energy concepts and thermal phenomena;

- prepare new materials for students in order to overcome the problems identified during the previous experimentation.

We introduced a new phase at the beginning of the sequence aimed at stressing the distinction between the quantities temperature, energy, heat and work while dealing with thermal phenomena. We suggest to consider with students different way to increase the body temperature (mechanical work, friction, heat, chemical reactions, lamp and microwaves radiation), and to show that it is possible to heat bodies without giving heat and to give heat without heating. We prepared, together with the teachers, three types of material: sheets for experiments; booklets for students' personal study and deepening of the treated topics; suggestions for teachers. Experiments are considered part of the scientific discourse on the topic, in a dialogue between theory, hypothesis and experiments. The booklets are not designed as handbook chapters, they want to be adherent to the experimental activities, resuming their particular aspects, by taking into account also what students have observed. The path is divided in three parts in order to facilitate its insertion in the usual curriculum: T (thermal phenomena), R (radiation), S (greenhouse effect). Moreover, we developed an introductory phase O to supply the knowledge on optics and waves necessary for the other phases.

We used these materials in four high school classes. The evaluation is still in progress. We noted that knowledge of basic energy concepts is necessary for understanding greenhouse effect, but also vice versa the study of greenhouse effect can be a useful *driving issue* for introducing basic energy concepts and phenomena. The experience has shown that it is important to overcome a too de-contextualized and technical approach to physics teaching. Using specific *driving issues* as foci of interest can promote the progressive construction of physics concepts and models. In particular, this topic (greenhouse effect and global warming or climate change) together with its intrinsic general interest (see IPCC 2007):

- offers an opportunity to clarify the distinction between work, heat, temperature, internal energy, radiation energy, concepts often confused by students, and to introduce schemes for representing energy fluxes and balances.
- focuses on the importance of reasoning in terms of energy balances to analyse stationary situations without thermal equilibrium. Situations of this kind intervene in various physics phenomena and are difficult to understand for students who often confuse transitory phases and steady state conditions.

7. Conclusions and Implications

Results confirm the importance of passing through all the cognitive steps mentioned in section 3. Presenting the entire explanation of the greenhouse effect in a unique step is not effective; the phenomenon is complex and needs a progressive rapprochement.

Students' reasoning is strongly influenced by the presentation they previously received of thermal phenomena and optics because they tend to reuse the same initial pattern for new situations even if not appropriate. To avoid this "imprinting" effect it is useful to present since the beginning a wide panorama of different situations, for example, to consider both situations of thermal equilibrium and non-equilibrium stationary situations, in familiar simple cases.

The successes and failures obtained in the class work and the analysis of the students' learning progression provided relevant inputs for challenging the persistent obstacles and misunderstandings and for revising some aspects of the TLS, in particular the presentation of basic concepts on thermal phenomena, including the stationary temperature situations in presence of radiation sources. Thus, a new cycle of implementation, analysis and refinement was activated in order to take into account effects and elements that only a contextualised practice could reveal (Design-based Research Collective 2003). To this purpose, we revised some aspects of the sequence, concerning the way of teaching basic energy concepts and thermal phenomena and we prepared new materials for students in order to overcome the problems identified during the previous experimentation and facilitate students' understanding.

A comparison between previous results and the new ones will help us to achieve a more precise picture of what elements can contribute to make it possible and profitable introducing a complex and challenging theme such as the anomalous greenhouse effect and global warming in the physics curriculum in high school.

Which Standards should Textbooks Meet to Support Competence Oriented Teaching?

Katrin, Bölsterli[1]; Markus, Rehm[2]; Markus, Wilhelm[1]

[1] University of Education, Central Switzerland, Lucerne
[2] University of Education, Ludwigsburg

Abstract: Textbooks are claimed to be one of the most important tools in the implementation of new school curricula. As there has hardly been done any research in the field of textbooks in German-speaking countries, our project focuses on the following question: Which standards should science textbooks meet in order to support competence oriented teaching in secondary schools?
To answer this question, a qualitative survey has been performed with 40 experts. This resulted in a checklist for teaching materials consisting of thirteen categories with 148 standards for teaching materials. These standards may support authors generating teaching materials as well as committees to enact newly published teaching materials. To make the assessment tool even more precise, it is planned to perform a quantitative survey with about 250 experts weighing the relevance of each standard.

Keywords: Textbook, teaching material, competence oriented teaching, science, secondary school

Background, Framework and Purpose

The role of textbooks and other teaching materials in science education is still significant. Why? Textbooks are the “resources most consistently used by teachers and their students in the course of the joint work."(Valverde, Bianchi, Wolfe, Schmidt, & Hounang, 2002, p. VIII). Despite this significance, there are hardly any ongoing studies in the field of textbook research in German speaking countries (Oelkers & Reusser, 2008).This can be illustrated by the fact that the newest empirically evaluated manuals for textbook analysis in German speaking countries were generated over 20 years ago. The two most famous ones are the “Reutlinger Raster [Manual]” (Rauch & Tomaschevski 1986, translated into English Rauch & Tomascheski, 1995) and the “Bielefelder Raster [Manual]” (Laubig et al. 1986). As a consequence, there are no research based standards available neither to write nor to legitimatize modern and competence oriented science textbooks and other teaching materials. To reduce this “research gap”, our project aims to setup empirically evaluated standards for science textbooks and teaching materials for secondary schools taking the upcoming competence and context oriented teaching approach into account.

Theoretical Framework and Research Question

The unsatisfactory results of the PISA and TIMSS studies have induced a reassessment of the Swiss school curriculum, especially in science. In order to implement the upcoming reform successfully, developmental work has to be performed not only on the assessment level but also on the micro-level of teaching (day-to-day management) (Gräsel & Parchmann, 2004). How can this be done? Valverde et al. (2002) mention that textbooks could support the

implementation on the micro-level as they “are commonly charged precisely with the role of translating policy into pedagogy. They represent an interpretation of policy in terms of concrete actions of teaching and learning." (p. VIII). This is supported by a survey in which persons who set up the curriculum mentioned that the curriculum influences to 64% the setting up of new textbooks and teaching materials (Bähr & Künzli, 1999).
Moreover, results from TIMSS attribute textbooks a strong influence on the test performance of students and hence affirm the crucial significance of textbooks (Valverde et al., 2002). Assuming that authorized textbooks for the new curriculum are lacking, teachers necessarily depend on their own idea of learning (Oelkers & Reusser, 2008). And given the fact that there is hardly any current empirical study in the field of textbook research in German-speaking countries (Oelkers & Reusser, 2008), our project is going to make a contribution to textbook research by answering the following question: Which standards should science textbooks meet in order to support competence oriented teaching in secondary schools?

Research Design and Methodology

A triangulation of methods is used to generate the standards for science textbooks and other teaching materials empirically. In the following section, the different methodological parts are described. For an overview see (Fig. 1).
After a pilot study, nine open questions were generated asking about different aspects of science teaching materials supporting competence oriented teaching. With a return run of 68%, 40 experts from three German-speaking countries answered the open questions. Experts were: authors, science educators, educationalists, publishers and science teachers with high professional competences. The answers of the experts were analyzed by the summarizing qualitative content analysis described by Mayring (2010).

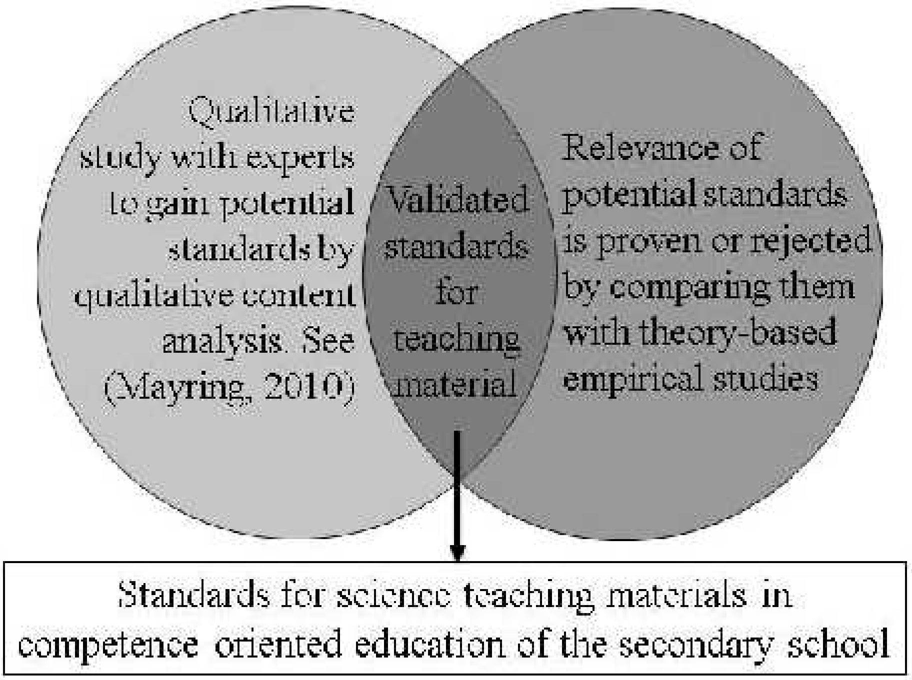

Figure 1: Methodological concept to obtain standards for teaching materials.

The potential standards obtained by the qualitative survey were checked for consistency by analyzing theory-based empirical studies (Fig. 1). This means that the standards were only

approved, if at least one theory-based empirical study in the field of science didactics, didactics and educational science supported the content of the standard.
For classifying the standards into categories, 23 existing "manuals for teaching materials" were scanned for interferences. In total, the following four classes were found (Table 1):
- Class 1: "The standards for teaching materials in general concern…" containing three categories.
- Class 2: "The standards for teaching materials taking competence oriented teaching into account, concern…" containing six categories.
- Class 3: "The standards for teaching materials focusing on the teacher's support, concern…" containing two categories.
- Class 4: "The standards for teaching materials focusing on the student's support, concern…" containing two categories.

In total, 13 categories were distinguished from one another (Table 1).

Results

By analyzing the answers of the experts and validating them with empirical studies, 148 standards were found. 16 standards in class 1, 83 standards in class 2, 24 standards in class 3 and 25 standards in class 4. For details see (Table 1).

Table 1: Theory-based classes and categories for classifying the standards

Classes and Categories	Standards
Class 1: The standards for teaching materials in general concern…	
…the fit to the own institution	4
…the fit to the curriculum	2
…the quality in general	10
Class 2: The standards for teaching materials taking competence oriented teaching into account, concern…	
…the scientific content knowledge	16
…the scientific skills	15
…the exercises and assignments	5
…the experiments	15
…the media	10
…the different parts of teaching materials	22
Class 3: The standards for teaching materials focusing on the teacher's support, concern…	
…the support of teachers for teaching	19
…the support of teachers for assessing the students	5
Class 4: The standards for teaching materials focusing on the student's support, concern…	
…the support of students to learn the content and skills	11
…the support of students with different proficiency levels	14
Total of standards	**148**

In the following, the formation of one standard is shown as a representative for all standards. This example belongs to class 2 "The standards for teaching materials taking competence oriented teaching into account, concern…" and the category "experiments" (Fig. 2).

Example of a standard in class 2 and the category: "experiments"
1) Standard uttered by an expert: Experiments which can be performed by the pupils in a self-regulated way are important.
2) Confirmation of the importance of the standard by theory-based empirical studies: First empirical study "In the view of the teachers, the main benefit of the jointly developed lesson plan was the … intense, self-

regulated, content-focused engagement of the students with theoretical topics from chemistry within a lab environment." (Witteck, Most, Kienast, & Eilks, 2007, p. 116). Second empirical study "The students mentioned that they had the feeling to have worked very intensely and to have learned a lot (item 3 and 5). The structure was considered very motivating and attractive (item 13). The positive consideration was based on two aspects. One is the cooperative learning atmosphere (items 4, 6, and 8), and the other was the highly self-directed activity (items 1 and 9), and especially the chance for self-regulated lab-work activities without being given a cook-book recipe that got the highest support (item 11 and 12)." (Witteck et al., 2007, p. 118).
3) Validated standard in the manual for evaluating competence oriented textbooks: Experiments to be performed in a self-regulated way are included in the observed teaching materials. Yes ☐ No ☐

Figure 2: Example of the genesis of a standard for teaching materials supporting scientific competence oriented teaching.

Conclusion and Implications

By triangulating the expert knowledge with theory-based empirical studies, 148 standards for teaching materials have been generated empirically. By comparing this manual with the most cited research-based checklists for teaching materials in the German speaking countries, which were both generated over 20 years ago, the "Reutlinger Raster" (Rauch & Tomaschewski, 1986) and the "Bielefelder Raster" (Laubig, Peters, & Weinbrenner, 1986), it can be shown that many things have changed. This means, that the change in the school system as well as the new media legitimates the research done for developing the new manual. In addition to the clear focus on competence oriented teaching, the new "manual for evaluating competence oriented textbooks" is to our knowledge the first research-based manual for competence oriented teaching. Moreover, the manual can be both used for authors as a research based scaffold to generating teaching materials and for committees to having a research based tool to enact new textbooks. To make this latter assessment tool even more precise, it is planned to perform a quantitative survey with about 250 experts weighing the relevance of the single standards.
Additionally, another study of our research team focuses on the use of current textbooks. Remembering the complaint of Oelkers and Reusser (2008) about the lack of current studies in the field of textbook research, these studies diminish this lament at least to a certain extent.

STUDY OF THE APPROACH OF ELECTRICAL CONCEPTS IN TEACHING PHYSICS AT COLLEGE (PROPOSALS FOR THE SYRIAN EDUCATIONAL SYSTEM COMPARED WITH THE FRENCH SYSTEM)

Chaza CHEIKH[1]

[1]S2HEP (Science and Society, Historicity, Education and Practice) ASM SIS – Health Individual and Society

Directed by: J. TOUSSAINT & N. ACIOLY-REGNIETR

Email: chazacheikh@live.fr

Abstract: As in all over the world, the Syrian educational system is influenced by social and cultural factors. Nowadays, a cultural movement has been established in Syria, which aims to improve this educational system.
In the context of a cultural exchange agreement between Syria and France, I was selected with others to come to France in order to obtain a PhD in physics Education which aims to construct useful suggestions to the Syrian system in comparison with the French system, to participate in the actual development of educational system in my country (Syria).
The motives of my research are to participate in this cultural movement in my country and to help improving as good as the methods teaching physics compared with another educational system which is the French system.
Therefore my thesis aims to suggest proposals of an appropriate curriculum in the Syrian context, these proposals will be based on the choice of scientific and social values presented explicitly in the "Syrian National scholar standards" as knowledge to be taught, taking into account the consideration of the essential role of teachers.
Today, Electricity has a major role in economical, scientific, technical field, in social practices and everyday life. Therefore, electricity has always been an important subject in the teaching of physics. So I chose to work on an introduction to electrical concepts (voltage, current, resistance ...) in college in Syria and also in France.

Keywords: Electricity, Curriculum, Syria, Teacher"s training, Students" learning success

INTRODUCTION

Recently, social, economic and environmental concerns have led many countries to develop new educational programs to face up to the enormous technical and economic development. According to a pragmatic approach, as societies are increasingly influenced by the ideas and products of sciences and technologies, all citizens in the future will be able to confront the problems if they have the base in scientific knowledge.

We aim, not only to allow students developing their scientific and technological knowledge, but also developing their roles in the modern society.

In this work, I introduce a contribution to the Syrian education system that improves the educational knowledge of students to enable them to understand and participate in the discussions of the modern societies.
I focus my work on the essential role of physics teachers training as major actors in this renovation, and also on the students‟ representations and conceptions as recipients of this renovation.

Theoretical framework

The theoretical framework of my thesis is based on a curricular approach of electrical concepts in teaching physics in college.
I start my research from the Syrian official documents (the curriculum and textbooks of physics in college). My objective is to concentrate on what already exists in these documents and to analyze the method in which we provide the physics in college. In particular how to present electricity and to search how we introduce the electrical concepts in college in Syria (place of experience, the model and modeling…).
Indeed, in Syria, we teach electricity by an electrostatic approach, we start by teaching the concepts of charges and electric fields. In dissimilarity, France has opted for an approach electrokinetic in teaching the concepts of short circuit and electrical current starting it from the fifth class.
The difficulties in learning electricity have been noticed for the Syrian students according to Syrian teachers. Also the Syrian educational program notes an immediate need to change their current mode of approach to introduce electricity in Syrian textbooks.
Thus, in my investigation, I opted for a comparative study between the Syrian and French educational systems; I rely on an approach of the process of didactic transposition, which is a complementary idea in a curriculum approach.
I found in my historical and epistemological study that there are several approaches to introduce the reference‟s knowledge.
Depending on the results of this study, I note the existence of three modes of approach in presenting the electrical concepts which I have found in international examples.
We can present the electrical concepts with a theoretical and mathematical method (Electricity and magnetism, Berkeley, 1965), or with a more concrete and real presentation of the electricity, called phenomenological way (the Feynman physics courses: Electromagnetism 1. Edition Wiley, 1979), or we can choose to provide the electricity in a more modern way, that is the phenomenotechical way (Bloomfiels, 2006).
In the new Syrian programs of 2005, I found that they focused on the role of students, and on the positive role that allows them to participate in the learning‟s operation, so they will not be a negative „‟Recipient‟‟‟.
As part of this curricular approach, and based on the researches of Closset JL (1983), J.Toussaint (2006), and Calmettes B. (1996), I will apply the idea of the “Curricular Martix”‟‟ (such as Kuhn T. identified in his article cited in the research paper of Jacques Toussaint‟ HDR) in teaching electricity in the Syrian context.

THE RESEARCH QUESTIONS

The overall objective of my research is to give useful proposals for the presentation of concepts in the electric field of physics learning in college in Syria. The purpose is to provide methodological tools that are likely to be valuable and effective in teaching electricity.
I will try in this work to find answers of the following question:

What proposals can be done to improve the Syrian educational system in comparison with the French system?
Based on the theoretical framework of this research, I will answer these three key questions:

- What are the respective characteristics of curricular approaches of the arrangement of electric concepts at school? What are the differences between these approaches? What choice of social and scientific values has been done to teach electricity?
- What training do we give to future physics teachers to teach electricity in college?
- What is the role that we must give to students in their learning?

METHODOLOGY AND DATA COLLECTION

I had in my Master‟s research paper, executed a historical study of the development of electricity in history (electrostatic, electrocinetics) since the first studies of Franklin up to now.
This study was followed by a study of the different approach to expose the electricity at the university level.
Then, during my first year as a PHD student, I executed a pre-analysis study of the contents of physics in college (programs, textbooks, accompanying documents, teachers guiding books….) in order to compare the method of introducing electrical concepts in the Syrian and French curriculum. The content analysis was effectuated according to the reproducibility rules and instructions and exchange between researchers and therefore a „‟quasi" objectivity.

a. The reporting contents

Based on the results of the previous historical and epistemological analysis, considering the three approaches of introducing electricity in the reference‟s knowledge (Mathematical approach, Phenomenological approach, and Phenomeno-technical approach), and to answer the research question and to realize our curricular study of electrical concepts, my research s‟ methodology is developed in three main axes:
In Syria, there is only one official textbook dedicated to each level of education. While in France, many textbook are available to teachers and students. So I have chosen three different editions of French textbooks that are commonly used in French schools (Micro-Mega, Hachette, Hatier).
I have chose the standard of analysis in order to compare the textbook in both Syria and France in terms of teaching the electrical concepts.
Thus, I have relied on the theoretical framework of my thesis with the three previous ideas by a process of didactic transposition (Y. Chevallard). I have tried to find a relationship between the three levels of knowledge (reference‟s knowledge, knowledge to be teach, taught knowledge) (Y. Chevallard, 1991).

b. The actors of the renovation : the teachers

In a second step, I complete this curricular study depending on the results of the previous analysis of the contents by focusing on physics teachers‟ training to define their conception in electricity through a questionnaire addressed to the college physics teachers in Syrian and France.
This questionnaire will be followed by audio interviews with the same teachers, asking them questions such as: what is the electricity in your opinion? What is the preferred method to teaching electricity in college?
I sent a questionnaire to physics‟ teachers in college in Syria in August 2011 and I got 24 answers.
In this questionnaire, the teachers answered scientific, methodological, and technological questions. The results are presented in the paragraph below (Results).

In France, I intend to choose for each edition of textbook 10 teachers to the questionnaire, so I will have 30 replies, and I will choose 10 teachers for the interviews, considered his experience in teaching, and the constraints that are likely to be encountered in this type of data collection. The questionnaire with French teachers will be distributed at the end 2011.

c. Recipients of the renovation: Students

The third axe of this curricular study is to analyze the mental representations of the electrical concepts for students.

I intend to distribute a questionnaire to students trying to find the difference between Syrian and French system, knowing that the introduction of electrical concepts in Syrian and French textbooks is very different from each other.

The results of these three methodological approaches will help me to identify the causes of these difficulties in learning electricity among Syrian students, and to define the type of problems (method of presentation in the programs or textebook, teaching method, social difficulties, etc). So I can at the end achieve my purpose in this research and I could thus make proposals for the teaching of electricity in my county.

PARTIAL RESULTS

Relying on our research questions, some ideas are emerging after the first experiment carried out.

a. Preliminary analysis of the Syrian and French official documents

In this preliminary analysis, I will discuss some points which I find interesting in my approach:

1. Orientation far from experimental method in the Syrian program but not in the French one (Syrian National scholar standards, 2007).
2. One textbook for each scholar level in Syria, but many in France.
3. Presentation close to the historical evolution of electrical concepts in the Syrian programs and textbooks, for example we begin our teaching of electricity in the fifth class in college with teaching the concepts of electric charges.
4. In the French side, the programs and textbooks have chosen to start teaching the concepts (simple circuit, electric current, etc.
5. In Syria, the phenomena exist in the scholar book to validate theories. In France, the situation has been addressed to find a solution.

From what I presented above, I found that there are several approaches to introduce electricity for students.

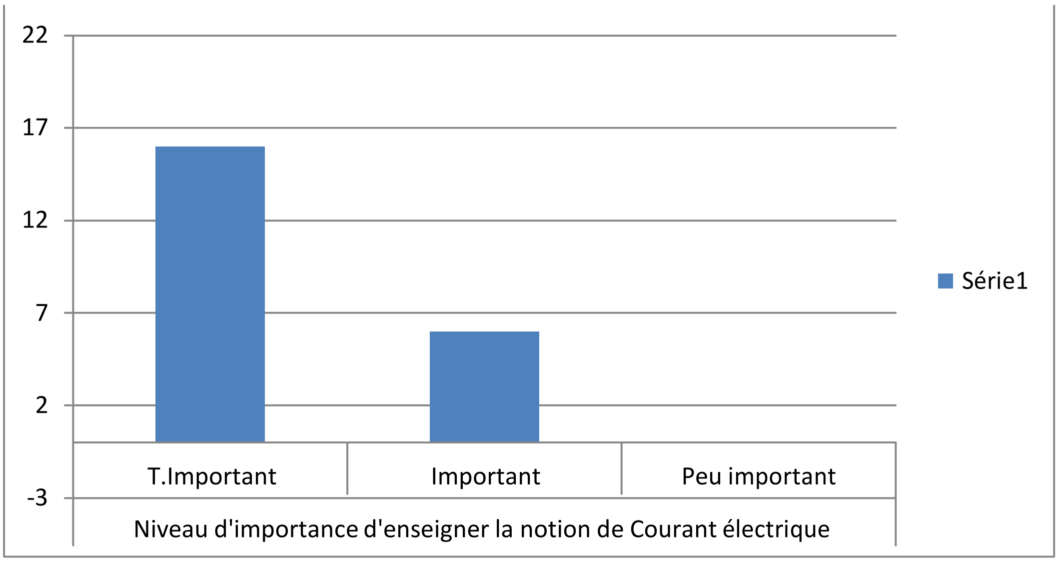
b. Analysis of the questionnaire given to physics teachers in Syria

I submitted a questionnaire to some Syrian physics teachers that are more interested points:

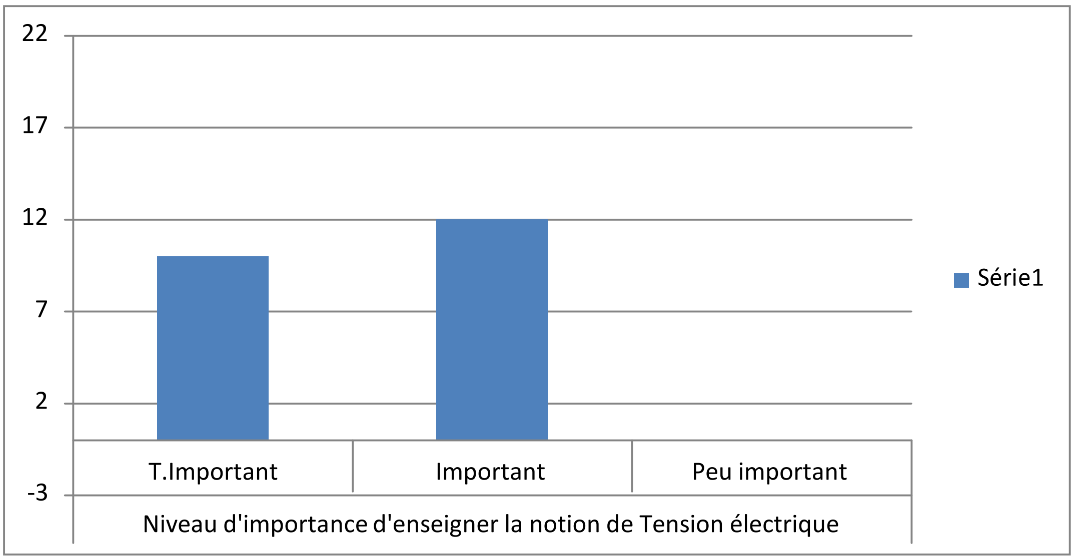
1. Concerning the answers of the question: “Have you ever had a didactic training?””: for Syrian teachers the didactic training is equal to one year pedagogical training which is proposed in the faculty of sciences education which prepare the future teachers who had the diploma in their specialties to teach in a public school.
   But the problem is that before 2005, it was not required for the competition of teaching in schools. It became obligatory in 2005. Therefore, we have identified more than 59% of the teachers interviewed had not had a didactic training, and

only teachers who had less than 5 years of experience have answered positively to this question.

2. Concerning the answer of the question: "what is electricity for you?": it was the **microscopic model** which appeared strongly in most of the answers. A **concretization** of the electrical concepts that appear in the word „"**Conductor**" that I found in several answers like this one: (Torrent of electrons path into the **conductor** in one direction).
   Also, teachers confuse the general concept of electricity with the concepts of electric current, and they forget to speak about the basic concept in electricity which is the concept of Voltage.
3. The two following histograms show that most of the Syrian teachers believe that the electric key concept is the electric current and not the Voltage.



Histogram (1) level of importance of teaching the concept of electric current in college in Syria



Histogram (1) level of importance of teaching the concept of Voltage in college in Syria

4. I found that over 50% of Syrian teachers agreed with the idea of teaching the concepts of electric current, intensity, and voltage concretely.
5. **Teachers** find **difficulties** in teaching the electricity, to overcome these difficulties and to help their students for a better learning of electricity, they proposed three ideas that seem to be useful and logical:
    a. **The experimental method** (forming un electric circuit, powering a lamp, etc).
    b. A **recourse analog** (such as the hydrolical analogy).
    c. Implement the teaching of electricity by giving **example from domestic devices, or natural phenomena**.

These results show an immediate need to develop the system applied in teachers training in Syrian universities to update their epistemological and didactical knowledge in the field of science education.

Of course, the tracks of analysis that we have mentioned above must now be studied and developed.

c. The next step will be devoted for students

MULTI-THEORETIC APPROACHES TO UNDERSTANDING THE SCIENCE CLASSROOM

David Clarke[1], Li Hua Xu[1], Jenny Arnold[1], Lay Hoon Seah[2], Christina Hart[1], Russell Tytler[3] and Vaughan Prain[4]

[1]University of Melbourne, Australia

[2]University of Gothenburg, Sweden

[3]Deakin University, Australia

[4]La Trobe University, Australia

Abstract: Multi-camera on-site video technology and post-lesson video stimulated interviews were used in a purposefully inclusive research design to generate a complex data set amenable to parallel analyses from several complementary theoretical perspectives. The symposium reports the results of parallel analyses employing positioning theory, systemic functional linguistics, distributed cognition and representational analysis of the same nine-lesson sequence in a single science classroom during the teaching of a single topic: States of Matter. Without contesting the coherence and value of a well-constructed mono-theoretic research study, the argument is made that all such studies present an inevitably partial account of a setting as complex as the science classroom: privileging some aspects and ignoring others. In this symposium, the first presentation examined the rationale for multi-theoretic research designs, highlighting the dangers of the circular amplification of those constructs pre-determined by the choice of theory and outlining the intended benefits of multi-theoretic designs that offer less partial accounts of classroom practice. The second and third presentations reported the results of analyses of the same lesson sequence on the topic "states of matter" using the analytical perspectives of positioning theory and systemic functional linguistics. The final presentation reported the comparative analysis of student learning of density over the same three lessons from distributed cognition and representational perspectives. The research design promoted a form of reciprocal interrogation, where the analyses provided insights into classroom practice and the comparison of the analyses facilitated the reflexive interrogation of the selected theories, while also optimally anticipating the subsequent synthesis of the interpretive accounts generated by each analysis of the same setting for the purpose of informing instructional advocacy.

Keywords: Classroom Research, Multi-theoretic Research Design, Science Education, Video-based Research

INTRODUCTION

As theories in the field of education continue to multiply and divide, it becomes increasingly urgent to determine how we can make use of this diversity to inform educational practice. The task of generating instructional advocacy from research findings that are grounded in different theoretical perspectives is a very challenging one, given the interdependency of theoretical choice and research findings. In carrying out classroom research, each theory affords particular analytical strategies, each focuses attention on specific aspects of the object or phenomenon under investigation but ignores other aspects. Inevitably, each should produce distinctive findings: the products of the particular analytical stance adopted. This theory-ladenness of observation has been recognized by researchers both from the field of philosophy of science and from social science (e.g. Guba & Lincoln, 1994; Kuhn, 1996), but only recently from the educational research community (e.g. Bikner-Ahsbahs & Prediger, 2006; Cobb, 2007). Tsaparlis (2001) argued that the use of various perspectives in science education, even potentially conflicting ones, could enrich our understanding of the teaching and learning of science. Clarke (2001) made a similar point in reporting a project in which a common data set drawn from eight science and mathematics lessons was subjected to analyses undertaken from ten different theoretical perspectives.

Since different research studies undertake data generation and analysis using different theories, the warrant that might be claimed for the consequent advocacy of any particular instructional action is contingent on the chosen theory/ies, among other considerations. In the research project that generated all the analyses reported in this symposium (Causal Connections in Science Classrooms – CCSC), multi-camera on-site video technology and post-lesson video stimulated interviews were used in a purposefully inclusive research design to generate a complex data source amenable to parallel analyses from several distinct theoretical perspectives (eg positioning theory, systemic functional linguistics, distributed cognition and representational analysis). The particular combination of theories was strategically constructed to provide complementarity of perspective such that each theory accorded emphasis to different features of classroom practice. Each theory, although being applied in the analysis of the same setting, offers distinctive insights reflective of the theory's foregrounded constructs.

This symposium reported the results of parallel analyses employing positioning theory, systemic functional linguistics, distributed cognition and representational analysis of the same nine-lesson sequence in a single science classroom during the teaching of a single topic. While each analysis is demonstrably valuable in itself, in combination, these results demonstrate the partiality of any single theory or theoretically-driven analysis in attempting to capture the complexity of the science classroom and the corresponding need for inclusive multi-theoretic research designs.

A LESS PARTIAL VISION: BENEFITS AND CHALLENGES IN A MULTI-THEORETIC STUDY OF ONE SCIENCE CLASSROOM[1]

A key aspiration of classroom research is the generation of empirically-grounded instructional advocacy. Since different research studies undertake data generation and analysis using different theories, the warrant that might be claimed for the consequent advocacy of any particular instructional action is contingent on the chosen theory/ies, among other considerations. In this symposium, rather than considering convergence or compatibility as the definitive result of the particular combination of theories, we focus on the compatibility of the interpretive accounts generated by their application to a common source of classroom data. In attempting to meet the challenge of providing evidence-based instructional advocacy, we address the question "under what conditions are the interpretive accounts compatible?" In this context, compatibility of the interpretive accounts would strengthen the authority of any recommendations for instructional practice arising from that research. We suggest that such compatibility must be considered as contingent on the events, objects or actions being analysed and on the specific question being addressed by the analysis. This contingent compatibility focuses our attention on the use of theories as interpretive tools.

Multi-camera on-site video technology and post-lesson video stimulated interviews were used to generate a complex data source amenable to parallel analyses from several complementary theoretical perspectives. This approach was intended to realize two very specific aims:

[1] This section summarises the first presentation by Clarke and Xu.

(i) Understand the setting: to maximize the sensitivity of the combined analyses to a wide range of classroom actions and learning outcomes, and

(ii) Understand the theory: through the combination of theoretical perspectives, examine the extent to which the results of analyses employing various theories and the theoretically-grounded explanations of these results are complementary, mutually informing, or, perhaps, incommensurable.

Science classrooms offer a rich educational environment, providing recordable instances of language use, a variety of classroom organizational groupings, varied instructional practices (demonstration, lecture, whole class discussion, and collaborative group work, both experimental and reflective), the utilization of a variety of artefacts (both physical and conceptual), the potential for ontological, epistemological, ethical and moral tensions to emerge, and, arguably, a highly diverse range of learning outcomes. It is this richness and complexity that offers the greatest potential for the interrogation of current theory and that also poses the greatest methodological challenge.

Data Source and Data Set

The focus of the parallel analyses reported in this symposium was a seventh grade science class of twenty-seven students (11 girls and 16 boys) aged between twelve and thirteen years. Data generation employed a four-camera approach (Teacher camera, two Student cameras, Whole Class camera), including onsite mixing of camera images into split-screen video records used to stimulate participant reconstructive accounts of classroom events in post-lesson student and teacher interviews (adapted from Clarke, 2006).

Figure 1a. Video material for student interview [Student camera: Teacher camera]

Figure 1b. Video material for teacher interview [Teacher camera: Whole class camera]

The video stimulus for a student interview consisted of a synchronized split-screen display of the video images generated by the teacher camera and the camera focused on that student and her nearby classmates (Figure 1a). The teacher viewed a similar composite video combining the teacher camera and whole class video images (Figure 1b)[2]. Additional data generated for each lesson consisted of copied or scanned written material (teacher planning material, student notes, textbook and worksheet pages, and test material) and observational notes made in the classroom by four researchers, three of whom were responsible for conducting the post-lesson interviews. A sequence of nine lessons was recorded, constituting the topic “States of Matter.”

Formal data generation was preceded by two ‘familiarization’ lessons, in which all aspects of the data generation process were conducted for the dual purposes of familiarizing classroom participants with data generation procedures and familiarizing the researchers with the spatial configuration of the classroom and the typical interactional patterns and movements of the participants (camera positions relative to teacher and student locations are shown in Figure 2).

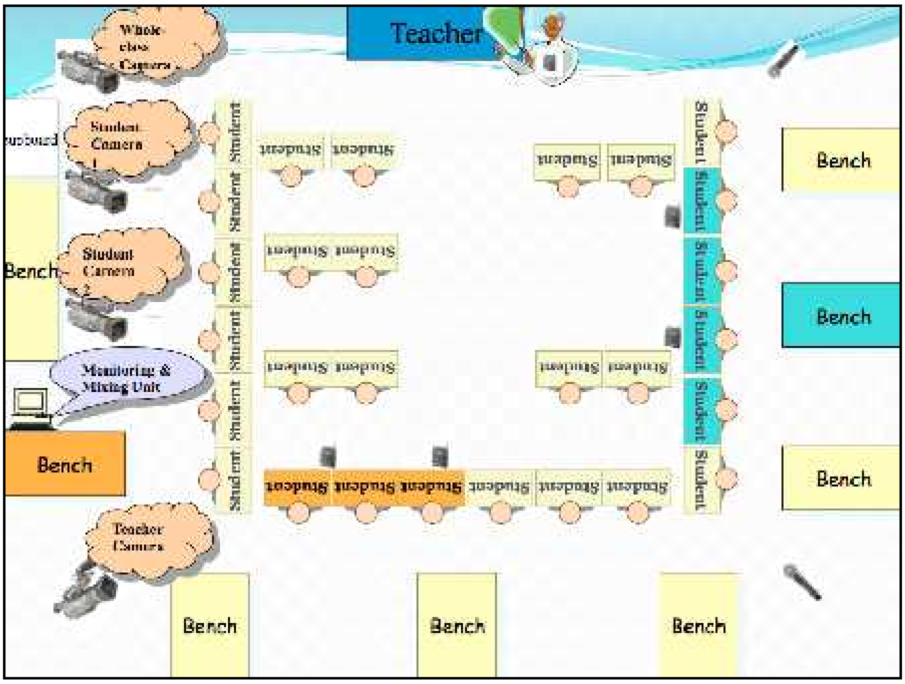

Figure 2. Classroom Layout showing camera configuration and radio microphone locations

We have an obligation as researchers to accept responsibility for the constructed nature of our data – and, of course, to document the process of data generation, identifying the points at which decisions were made regarding inclusion and exclusion. This is not always easy – particularly when the acts of exclusion are made for us by the technology, the method, or a theoretical frame that attends to some aspects of the setting and ignores others. In a multi-theoretic design such as the one employed in this project, we distinguish the “data source” constructed to anticipate and accommodate the parallel analyses from the data set reconstructed from that data source by each individual researcher for the purpose of a specific analysis.

Analysis and Synthesis in Multi-theoretic Research Designs

Each of the researchers participating in the CCSC project applied their own analytical perspective in order to select elements within the data source, thereby generating a distinct data set for each of the intended analyses. Each data set, so constructed, was then analysed using the same theoretical framework that guided the construction of the data set. In this

[2] For ethical reasons, actual images of the teacher and students cannot be shown. Images of students and teachers in both Figures 1a and 1b are simulated images developed for the purpose of illustrating the material used in the video-stimulated interviews.

respect, each analysis resembles any mono-theoretic research design in that the constructs privileged by the chosen theory were matched to data types and a research design constructed that employed methods suitable for the generation of the targeted data. Each independent analysis remained vulnerable to the same accusation of circularity or pre-determination that can be leveled at any mono-theoretic research design. Once available, however, the results of the parallel analyses can serve several purposes:

(i) By addressing different facets of the setting and thereby providing a richer, more complex, more multi-perspectival portrayal of actors and actions, situations and settings;
(ii) By offering differently-situated explanations for documented phenomena and differently-situated answers to common research questions;
(iii) By increasing the authority of claims, where findings from different analyses in relation to the same question or the same phenomenon were coincident;
(iv) By qualifying the nature of claims, where findings in relation to the same question or the same phenomenon were inconsistent or contradictory;
(v) By providing a critical perspective on the capacity of any particular theory to accommodate and/or explain particular phenomena, in comparison with other theories employed in analyses related to the same events in the same setting;
(vi) By facilitating the synthesis of the results of the parallel analyses for the purpose of informing instructional advocacy.

The derivation of all findings from the same data source through the application of all analytical approaches to the same setting greatly strengthened the project's capacity to realise these six purposes. In particular, multi-theoretic research designs integrate the activity of research synthesis into the research design as an essential element. The goals of research synthesis (Suri & Clarke, 2009) should not be limited to normative convergence on some form of best practice. In developing instructional advocacy arguments, it may be the identification of contingencies on any recommendations that offers greatest utility, by identifying combinations of context and action most likely to promote locally significant outcomes. Multi-theoretic research designs are intended to inform both theory and practice.

"I DON'T PAY ATTENTION THE WHOLE TIME": SCIENCE STUDENTS NEGOTIATING SOCIAL IDENTITIES AND PRACTICE[3]

This section reports findings from a study that sought to identify the circumstances under which participating students were positioned as agentic, and it supports an argument for a discursive approach to the study of agency.

Studies of student agency in science education have previously adopted ethnographic methodologies, using interviews and observations of particular students both in an out of their science classrooms in order to: a) determine the student's goals for the future, b) observe the student's actions that aligned with the student's goals and, c) determine the state of affairs both before and after student's actions in order to detect change related to the achievement of the student's goals. Based upon the ethnographic evidence, researchers have constructed students in research accounts as responsible for their actions and for bringing about changes.

Rather than assigning responsibility to students as described above, this study, in recognizing the constitutive force of language (Harré, 1992; Potter, 2001), sought to investigate science classroom discourse and identify moments in which students indexed responsibility to themselves. Of interest in the study was whether or not actions that the students indexed to

[3] This section summarises the second presentation by Arnold.

themselves as a responsible agent were taken up as legitimate in the classroom discourse. Therefore the response of others was taken into account in the discursive analysis of meaning making as the realization of classroom storylines and positionings.

Data Generation and Analysis

The research was conducted as an instrumental case (Stake, 2005) and the main source of data were the video recordings described earlier. The year-seven science class occurred at a large, multi-ethnic, suburban, government secondary school in Melbourne, taught by an experienced and well-regarded science teacher. As noted, the science lessons were filmed for the duration of an entire unit of work on ‘The States of Matter’. The research took place in the last term of the year.

Focus students for this analysis were three female students, who had been very successful in science assessment tasks throughout the year, and who habitually worked together during small group tasks. The focus students wore microphones on lanyards during the lessons and participated in video-stimulated, post-lesson interviews on a rotating basis. These interviews, the researcher’s observational notes, copies of lesson planning documentation and work produced by all students in the class provided supplementary information for clarifying meaning in the classroom discourse.

The audio tracks from all videos were transcribed. Conversations about science or whilst doing science in which the focus students participated were selected for the study. Phonological transcripts of these conversations were generated as data for the study.

A coding system, drawing upon the work of Muhlhaüsler and Harré (1990), was developed by the researcher for the purpose of identifying speech-action in which the focus students indexed responsibility to themselves. The coding system was based upon indexical features of our language that speakers can use to index their responsibility such as pronoun use, modality and tense, and together these grammatical features have been called by the resesarcher ‘the grammar of agency’.

The meaning of the students’ language use was analysed in the context of the conversational episode in which the students used the grammar of agency. Meaning was analysed using discourse analysis in social psychology (Harré & Langenhove, 1999a; Wood & Kroger, 2000), and in terms of the storylines and positionings that were realized jointly by the participants in the conversation. Nine of these conversational episodes were used to communicate the findings of the study because they exemplified variability in the way the girls indexed responsibility to themselves and were representative of the way in which the girls’ actions were taken up by others in the classroom discourse.

Results

This sample analysis focuses on one of the focus student’s (Tasha’s) use of the ‘grammar of agency’ to position herself and her friends as responsible for actively seeking the scientific knowledge. Tasha had identified the knowledge she lacked and pursued the knowledge by asking her friends, *“What is the Particle Theory?”.* However, her friend, Kesar’s response was, “You’re seri(h)iosly asking me that?”. The social force of Kesar’s utterance was Kesar’s repositioning as not responsible for knowledge seeking. Subsequent to Kesar’s repositioning, Tasha published the biographical “small story” (Bamberg, 2004): *“I don't pay attention the whole time… seriously! I haven't heard about the Archimedes in the bathtub thing”*, which had the function in the conversation of repositioning Tasha in alignment with her friend. The biographical story was face-saving for Tasha and the dominant storyline in their conversation became, ‘Students’ as responsible for passively receiving scientific knowledge’. The analysis of the function of Tasha’s biographical story illustrates the importance of the distinction made by discursive psychologists (Harré & Langenhove, 1999b) between the storying of oneself in autobiography and the realisation of one's position in an ongoing conversational storyline for the development of one's social identity and the realisation of social practices.

Discussion

The girls' actions can be understood in terms of a conversational background in which their social identities as members of a student group who were not expected to know the particle theory were realised. Rather than expressing her own lack of knowledge of the particle theory, Tasha's statements *"I don't pay attention the whole time… seriously! I haven't heard about the Archimedes in the bathtub thing"* were practically orientated towards maintaining solidarity with this student group.

In this way, the collectively realised classroom practices constrained Tasha's development of a social identity as an active seeker of knowledge. Her social identity as a knowledge-seeker was not taken up as viable within the girls' small group and was not published beyond their small group, limiting her opportunity for being positioned as agentic. The findings of the study suggest that reflexive attention to student inquiry and collaboration could enhance opportunities for students to be positioned as agentic. This is supported by Mercer and his colleagues (eg Mercer, Warwick, Kershner, & Kleine Staarman, 2010), who found that the teacher's "vicarious presence" was an important factor in determining the degree to which students engaged in collaborative, dialogic activity.

A goal of this study was the development of a "workable" definition of student agency as a form of discursive practice in which students are positioned as responsible agents. The focus of this study was a discursive psychological account of the variability in agentic positioning by three academically successful science students. By focussing on agency as a discursive practice it was possible to show that the participating students' opportunities for developing social identities as responsible agents within science was constrained by their joint action directed towards the passive reception of scientific knowledge. This illustrates the potential utility of a discursive approach in studying agency and supporting reform efforts in science education directed towards student inquiry and dialogic activity.

STUDENTS' LANGUAGE USE AND ITS RELATION TO THE REQUIREMENTS OF SCIENCE INSTRUCTIONAL TASKS[4]

This linguistic analysis was motivated by an interest in understanding the challenges that students face when appropriating and employing the language of school science in the classroom context. There are at least three assumptions underlying this study. The first and foremost assumption is that learning language of school science is constitutive of learning science (e.g., Lemke, 1990). This assumption provides the main impetus of this study. The second assumption is that learning in the science classroom involves learning its social practices, of which responding to instructional tasks constitutes an important aspect. A third assumption is that the use of language is situated and functional, which implies that language use can vary with the requirements of a task. This assumption is in line with the use of Systemic Functional Linguistics (SFL) framework as the analytical lens (Halliday, 1994).

In this study, each written explanation from students was first examined at both content and lexicogrammatical (LG) level. Subsequent to both content and LG analysis, we compared and contrasted a set of explanations found in students' practical reports with another set of explanations found in their test papers. This method of comparison involved the identification

[4] This section summarises the report authored by Seah, Clarke & Hart

of qualitative differences in language use between the two sets of explanation that might be related to the specific requirements of each task.

The analysis was guided by the following research questions:

1. What are the similarities and differences in the students' use of LG resources between the two tasks?
2. What are the similarities and differences in the requirements between the two tasks?
3. What are the possible connections between the students' language use and the requirements of the tasks?

Data Generation

Among the data generated, the most relevant for the present study were two sets of written explanations completed by students. Below is a description of the source of these explanations:

I. Practical report on expansion

Mr. Gardiner distributed a practical worksheet, which described three activities:

Activity A: Students were required to pass a metal ball through a ring before and after heating (an example of expansion of a solid).

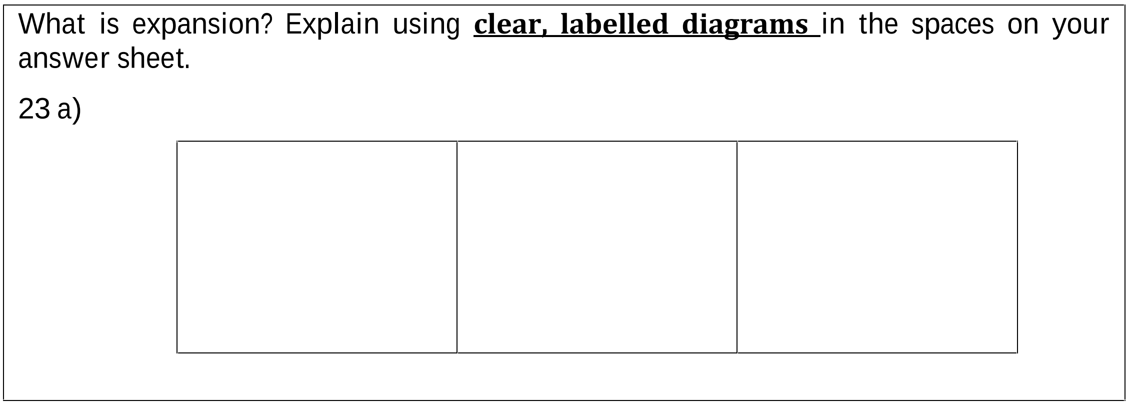
Activity B: Students were asked to fill a flask with coloured water and fit a stopper with a piece of glass tubing through it, before putting the flask in a container of hot water for a few minutes and then subsequently in a container of cold water (an example of expansion of a liquid).

Activity C: This involved heating with a Bunsen flame an empty conical flask, the mouth of which was covered with a deflated balloon (an example of expansion of a gas). Unlike the two activities above that were performed by the students themselves, this activity was demonstrated by the teacher.

For each activity, the students were told to record in their practical book: (i) their prediction of what they thought would happen; (ii) their observation of what happened; and (iii) their explanation for what happened.

II. Test item on expansion

A week after the practical task on expansion, the students sat for a test on the topic "States of Matter", which included a test item on expansion (see Figure 3). As with the practical task, this test item required students to provide an explanation. Data from the lesson videos and interview videos constituted supplementary data useful for understanding the context and for triangulating the meanings ascribed to the written language.



What is expansion? Explain using **clear, labelled diagrams** in the spaces on your answer sheet.

23 a)

Figure 3: Test item on 'What is expansion?'

Analysis

1. Content analysis I: Classifying all students' explanations according to their content using different coding categories referred to as "explanatory foci". Altogether, three explanatory foci - each addressing a specific aspect of expansion – were identified from among the two sets of explanation:

- Macro reference: represented expansion at a macro-level by describing the perceptible aspects of the phenomenon;
- Submicro reference: represented expansion at the submicro-level by interpreting the phenomenon in terms of the particle model of matter;
- Causal reference: invoked a cause (e.g., an external agent or a condition) that brought about the expansion.

2. LG analysis using SFL: The following analytical categories from the SFL perspective were utilised to classify the LG resources employed by the students into linguistic classes:

- *Process*: is typically expressed by a verb or a verbal group and is associated with a small set of *Participants* such as *Medium*, *Agent* and *Range*
- *Medium*: is typically expressed by a noun or a nominal group and is the indispensable *Participant* without which the *Process* would not 'exist'; both the *Process* and the *Medium* constitute the core of the clause, which is the unit of the LG analysis
- *Agent*: is also typically expressed by a noun or a nominal group and is 'the entity that does or acts; the cause or instigator of a process' (Lemke, 1990, p. 222)
- *Range*: can be expressed by a noun or an adverb and refers to 'the limits, extent, or nature of what the process does' (Lemke, 1990, p. 222)
- *Circumstance*: is prepositional phrase, adverbial group, or nominal group that express the circumstances (e.g., of reason, of condition, of location, of means etc.) associated with the *Process* or the *Participants*

These linguistic classes enabled us to differentiate the function that LG resources served to realise scientific meaning. LG analysis highlighted the similarities and differences in the use of LG resources among the students' explanations, facilitating the next phase of analysis.

3. Content analysis II: This phase involved identifying the diversity of meanings realised within each explanatory focus.

Findings

Several ways in which the task requirements might have shaped students' use of LG resources were identified. Specifically, the similarities between the tasks (e.g., the focus on expansion and the requirement to "explain") might have contributed in part to the following similarities between the two sets of explanations: the presence of the same three explanatory foci; the same explanatory focus being associated with a common set of LG resources and addressing the same aspect of expansion; and the same diversity in the types of explanation found among the responses for each task. On the other hand, the differences in nature between the tasks (e.g., specific instance of expansion versus expansion in general; no request to use diagrams versus with such a request) might have contributed to differences between the two sets of explanations that included: the presence/absence of purely causal type of explanation; the diversity of instances of expansion; the presence/absence of certain scientific meanings; the frequency of LG resources employed to link the various explanatory foci together; and the frequency of "it" being employed indiscriminately.

From the findings, we can postulate several mechanisms through which the students' language use might have been shaped by the requirements of a task. In the case of the practical activities, the task determined the observations expected and these in turn shaped what and how particular LG resources were employed. The way students employed LG resources could also be mediated by the students' interpretation of the requirements of the task and their awareness of the differing requirements of the various tasks. The role of the task itself in shaping students' use of LG resources suggests that learning the specific requirements of science tasks is part and parcel of 'the ways of knowing and practices of school science' (Driver, et al., 1994, p. 11) that students need to be 'enculturated' to successfully integrate into the community of the science classroom. For instance, the diversity of the students' explanations in terms of types in both sets of explanations suggests that some students were not clear about what it meant to explain in the context of a science task. As students may have varying interpretations of what a task asks of them, teachers may need to discuss and explicitly unpack the requirements. This study shows that by exploring the possible ways in which a task can shape students' use of LG resources, we can expand our understanding of the challenges that students face when they are required to employ the language of school science in the classroom context. Finally, an understanding of how the requirements of tasks could affect students' responses may also assist in lesson planning by suggesting what kinds of task could be suitable for different stages of instruction.

DISTRIBUTED COGNITION VS. REPRESENTATIONAL PERSPECTIVES ON A CLASSROOM SEQUENCE ABOUT MATTER[5]

Comparison is made between two distinct analyses of the same sequence of science lessons on the topic of matter, involving macroscopic and particle ideas, the first using distributed cognition and the second a representational, semiotic perspective. Through such a comparison, an attempt is made to explicate some key similarities and differences of the two theoretical lenses that could afford a better understanding of the affordances of each theory and how each of them could contribute to advancing our thinking about science teaching and learning in classrooms.

Data Generation and Analysis

The lessons analyzed formed part of a three-lesson sequence on the topic of states of matter, but with a specific focus on the concept of density. The concept of density was only addressed in Lesson 2 and Lesson 3. Lesson 1 provided some background information regarding what the students knew about the three states of matter and the particulate nature of matter, which had some influence on student interpretation of density in the two lessons that followed.

Distributed Cognition

Key to the analysis is the interplay between student prior knowledge, the resources made available in the classroom (including physical, conceptual, and symbolic artefacts), and processes (for example, classroom discussion, teacher demonstration). The key question in the DCog analysis is how the interplay between the three components contributes to changes in patterns of interaction (such as ways of seeing, talking and thinking). The analysis of learning outcomes focused on the work of four male students, who worked together throughout the sequence. It is useful to outline briefly the key instructional acts undertaken during the three lessons in question:

1. An official definition was introduced by the teacher, drawing student attention to the formula on a worksheet. In the formula, density takes the form of mass being divided by volume;

2. To illustrate the meaning of density, the teacher presented two blocks of metal to the class: lead and aluminum. Both blocks were cubic in shape and of the same volume (see Figure 4).

[5] This section summarises the presentation by Xu and Tytler

As the teacher explained in the post-lesson interview, the demonstration of the two blocks was intended to show that the size of an object does not matter but substance matters. The two metal blocks served as an important cognitive artefact for student sense making of the density concept. Cognitive artefacts, in DCog terms, are man-made physical objects for the purpose of aiding, enhancing, or improving cognition (Hutchins, 1995). In this case, the two blocks provided a physical embodiment of the concept of density;

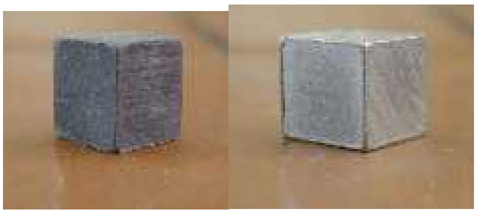


Figure 4. The two metal blocks (lead and aluminum)

3. A third event in the density lessons was the practical activity on measuring the density of a candle and a marble. According to the post-lesson teacher interview, the practical activity was intended to allow students "to get a physical feel for a concept", and "to introduce the term density as mass divided by volume" [0:18:10, L02-INT_T]. In this practical activity, one of the focal artefacts was the worksheet on measuring the density of two objects: a candle and a marble, which set out the aim, materials, methods, and questions for discussion. Like other cognitive artefacts (e.g. the two metal blocks), the practical worksheet was created with an intention to influence the practice of the user in particular ways. This worksheet prescribes the procedures for measuring the density of a candle and a marble, and it serves two main functions: as an instructional device that guides student action and as an inscription device that documents experimental results.

The DCog analysis highlights the important role of different artefacts in mediating student participation in collective activities and student sense making of science. The employment of physical artefacts, such as the two metal blocks, served as a common referent for anchoring the classroom discussion on density. The presence of the two metal blocks also enabled the students to interact with the abstract scientific concept in a concrete way by directing their attention to the features of the two blocks that were made relevant in the classroom interactions. In particular, it gave emphasis to the mass and the number of particles in determining the density of an object, which were later appropriated by many students to be the key determining factors for the density of a candle and a marble. On the other hand, the presence of the two blocks blinded the interlocutors (the teacher and the students) to a potential mismatch in their focus of attention: the density of an object and the density of a substance, since they assumed that they were referring to the same thing. Despite the teacher's intention to show that density depends on the substance of an object, both the teacher demonstration and the student practical work drew student attention to the specific properties of an object, such as mass and volume. It can be argued that underlying the difficulties in understanding the macroscopic and microscopic relationship is the lack of emphasis on the notion of "substance", which could potentially provide a conceptual bridge between the macroscopic and the microscopic properties (see Xu & Clarke, in press, for a more complete analysis of the two lessons on density).

A Representational Perspective

Recent work has focused on the need for students to be guided to construct and negotiate representations as part of learning to reason with these epistemic tools (Hubber, Tytler & Haslam, 2010; Waldrip, Prain & Carolan, 2010). Pragmatist perspectives (Peirce, 1931-58) have been used to interpret student learning and reasoning in terms of the triadic relationship between meaning making, multiple representations and their real world referents. This research analysed the learning environment in terms of challenges and supports it afforded students to coordinate the multiple representations involved in constructing explanations of density and the properties of matter.

The teacher's stated main aim in these lessons was to establish the macroscopic, mathematical definition of density through the formula D=M/V. From the perspective of Peirce's triadic model of meaning making, this involves linking the representation (the formula) with the real world referent in a 'weaving' process by which the capacity of the representation to make sense of phenomena is evaluated and its meaning refined through use.

Analysis of the video record of the three lessons related to density demonstrated the multiple representations that were introduced by the teacher to establish the meaning of the term. These included mathematical formulation of the mass-volume relationship, tabular representation of mass, volume and density associated with an experiment, role play of particles to establish differences between solids, liquids and gases, verbal and written explications, as well as the use of physical artefacts such as the aluminium and lead 'density blocks'. The analysis has illustrated the complex coordination of a series of partial and selective representations necessary to achieve a flexible understanding of density, and the demands this coordination places on teachers to support students in apprehending the features and purposes of the representations, and in making connections between them. Analysis of the representations, demonstrated:

- The need to explicitly support students in understanding the form and function of the various representations and the cost in this sequence of presenting each representation without adequate framing and negotiation;
- The need to frame student challenge activities to allow them to adequately explore and evaluate representations as making sense of perceptual phenomena, and the cost of having scripted, limited opportunity to do this. Thus, for instance, the mathematical expression for density was not utilized by students in a way that demonstrated its capacity to make sense of patterns of mass, volume and flotation in a range of materials;
- The need to acknowledge the selective nature of representations and the need to support students to coordinate a range of representations across different modes, rather than have them introduced and discussed largely independently and with limited reference to each other.

The representational analysis demonstrates the complexity of supporting student understanding of the density concept, and provides an interpretation of the difficulties recognized in the literature (confusion between substance and object, of difficulty of dealing with ratio, and of difficulty with particle ideas) as being fundamentally representational in nature. The teacher in this sequence introduced a range of potentially powerful activities including particle role-play, practical experiences, a tactile demonstration and extended discussion. However, perhaps due to time constraints, and because of the way the open classroom discussion was diverted by students' unanticipated exploration of particle ideas, there were limited opportunities for consideration of the form and function of each representation of density or of the way they interrelated. From a representational perspective this imposed severe limitations on the achievement of a flexible understanding of density.

Discussion of the comparison of Distributed Cognition and Representational Analyses

The first point to make about the two theoretical perspectives is that they focus on different units of analysis. DCog theory was developed to explain the way knowledge and learning are distributed within and across systems, in this case the classroom system, whereas the representational perspective focuses more centrally on the nature of individual meaning making, leading to consideration of how representational resources are opened up in the public space to support this. The DCog perspective highlights the mismatch in the focus of attention between the teacher and the students, and the limited connection between the macroscopic and microscopic views of density. The representational perspective highlights the mismatch as a lack of explication and negotiation of the multiple representations through which density is understood. But each perspective has its own limitations. Distributed cognition arose from studies of workplace settings, and therefore lacks a pedagogical view about how things should be or could be in the classroom. The representational perspective, on the other hand, has a strong literacy focus, but is less well developed to analyze situations involving many physical resources, such as science practical work. The two theoretical perspectives together provide a richer interpretation of the classroom practice studied.

Both theories come from a socio-cultural perspective that acknowledges the role of a variety of artefacts including language and inscriptions, in mediating learning, or generating meaning. The theories differ however in the emphasis they place of aspects of the classroom processes. Thus, while the representational perspective properly includes physical artefacts as having representational value, its focus has tended to be on multimodal inscriptions of various kinds as part of the argument for a literacy based perspective on learning and knowing. The aluminium and lead density blocks figure significantly in both analyses, and both theories concern themselves with their meaning in use, but their role is perhaps more naturally emphasized within the DCog perspective. This is because of the historical emphasis of DCog on how physical tools and other kinds of artefacts can transform the nature of the tasks to be performed by people.

The two theories allow distinct perspectives on teaching and learning, together providing a richer interpretation of the sequence than either on its own. The two analyses uncovered different perspectives on the relationship between physical and conceptual artefacts mediating learning, and on the nature of student learning and understanding. It is argued that such an analysis, utilizing a common data set, allows us to better understand the particular affordances of each theory and how constructs such as ‘artefact’, ‘representation’, ‘conceptual’, or ‘coordination’ sit in different relations to each other within the two theories.

CONCLUDING REMARKS[6]

In this symposium, we provided a demonstration that the theoretical choice one makes not only constrains the particular type of questions that one can ask and the particular type of phenomena that one can investigate, but also orients one towards providing a particular line of explanation for the question under investigation. We have illustrated this with parallel analyses of the same classroom events. These parallel analyses illustrate the capacity of each theory to address the connection between learning and instruction, to accommodate and to predict the likely benefits of particular instructional approaches.

The explicit comparison of analyses undertaken using Distributed Cognition and Representational perspectives has implications for the CCSC project’s goal of facilitating the interrogation of theory (as well as the illumination of setting and process). Specifically, the two theoretical perspectives (Distributed Cognition and Representational Analysis) occupy the same cognitive territory, and to a large extent have overlapping histories in their adherence to material interpretations of knowledge, and to notions of mediation. Unlike analysis involving positioning theory for instance, or systemic functional linguistics, which focus respectively on student agency and lexicogrammatical resources, DCog and

[6] These concluding remarks incorporate comments from the symposium’s discussant: Vaughan Prain.

representational perspectives both purport to deal with the way knowledge is constructed and enacted. These similarities throw up more sharply the relationship between the theoretical constructs, and the different foci, of the two theories.

The interpretations offered by the two theories appear in large part to be compatible, but their foci of attention of attention are different. For DCog, the distribution is across artefacts and people in a classroom, while Representational perspectives look at the way individual knowledge requires coordination of (is distributed across) multi-modal representational resources which are opened up and negotiated in the public space of the classroom. The two theories thus take a similar stance towards learning and knowledge, but from the perspective of the system, and the individual, respectively. The analyses informed by Positioning Theory and Systemic Functional Linguistics can also be distinguished by their foci of attention. Yet, the social realization of student agency and the use by those same students of lexicogrammatical resources are connected by the recognition that both activities are mutually constitutive of the students' engagement with the learning of science.

The interdependence of theory and analytical results has significant implications for our understanding of the role of theory in researching science classrooms. It is only through comparing the parallel analyses of data generated from a common data source that the core similarities and differences between theoretical lenses can be made explicit. In this way, new knowledge could be established with regard to how the various theories could possibly be compared or combined to inform research and practice. It is not our intention to challenge the value of research studies conducted from a single theoretical perspective. In fact, each presentation reports precisely such mono-theoretical accounts. The challenge is to integrate theories of the learning task, theories of learner attributes and theories of acquisition and participation processes in the cause of building theory or theory networks to inform classroom practice.

Our goal has been to explore some of the issues associated with the implementation of a multi-theoretic research design. If we are to progress as a community, we must develop methods by which we can contrast, connect and learn from our extensive and continuing research efforts. Multi-theoretic research designs attempt to exploit the value of analysing the same setting(s) from a variety of theoretical perspectives. We would like to suggest that the benefits include: increased insights, less partial portrayal, and the capacity to interrogate and refine both setting(s) and theories.

ACKNOWLEDGEMENT

This research benefited significantly from the funding provided by the Australian Research Council. The authors would also like to thank teachers and students whose participation made this research project possible. Lay Hoon Seah would like to gratefully acknowledge the Hasselblad Graduate School of Molecular Science Education, which provided the grant for her post-doctoral fellowship at the University of Gothenburg

THE IMPACT OF PHYSICAL EXPLANATIONS ON SECONDARY STUDENTS' KNOWLEDGE ACQUISITION IN THERMODYNAMICS

Antony Crossley & Erich Starauschek[1]

[1]University of Education Ludwigsburg, Germany

Abstract: In the process of science teaching, at some moment, some kind of explanation has to be given to the students. These explanations can vary in most different ways. One aspect is that different physical quantities can be used to explain the same phenomena. The objective of this research is to determine whether students' knowledge acquisition depends on the use of different physical quantities in the explanations.
In principle an experimental comparative study with pre-post design and follow-up test with two student groups was chosen. One student group used the physical quantities temperature and entropy to learn basic thermodynamics. The other student group used the physical quantities temperature and thermal energy. We must note that an uncommon concept of entropy was taught, which is based on students' alternative frameworks and not on concepts of statistical physics. To minimize confounding of the results by, e.g. the teacher variable, a computer based learning environment was designed and administered to N=184 secondary students at the age of 14 to 16 years in southern Germany. Knowledge acquisition was measured with a paper-and-pencil test and evaluated statistically using analysis of variance and analysis of covariance, considering students' previous knowledge as a second independent variable. The students instructed with explanations using the physical quantities temperature and entropy have a significantly higher knowledge acquisition.

Keywords: physics learning, thermodynamics, explanations, knowledge acquisition, physical quantities

1. BACKGROUND AND PURPOSE

In physics (e.g. in thermodynamics or mechanics), sometimes different physical quantities can be used to describe the same phenomena. In general, scientists choose those physical quantities which best provide the solution to a given problem. In science teaching, however, different physical quantities lead to different explanations because they trigger different mental representations and models. For students these explanations can therefore vary in difficulty. Hence, the question rises of whether the use of certain physical quantities with their associated explanations has an influence on students' knowledge acquisition. A long German research tradition about these questions exists. Some studies indirectly indicate this effect, as the underlying concepts of a given physical explanation do influence students' physics learning (e.g. Herdt, 1990; Wiesner, 1994; Gleixner, 1998; Bader, 2001; Starauschek, 2001; Wilhelm et al., 2010). However, almost all of these existing studies, except Wilhelm et al. (2010), are confounded with extraneous variables, e.g. the teacher variable. In our study we have tried to eliminate this problem by using a computer based learning environment to be able to measure exactly the effect of the variable "physical explanation" based on the choice of physical quantities.

2. RATIONALE

Two different approaches for teaching senior high school students basic thermodynamics are compared. Usually, the physical quantities “temperature” and “heat” are used to describe and explain thermal phenomena. One of the key problems in using the physical quantity heat is the term’s different meanings in physics and in everyday language (e.g. Kesidou & Duit, 1993). Even after learning thermodynamics students do not differentiate between the physical quantities of temperature and heat and remain in their alternative (everyday) frameworks (e.g. Kesidou et al., 1995). Alternative approaches teaching thermodynamics use the physical quantities of temperature and entropy (Job, 1972; Herrmann, 1998) or temperature and thermal energy (Muckenfuß & Nordmeier, 2006, 2007). Here, students’ alternative frameworks are addressed in two different ways. First, the extensive aspects of the everyday meaning of “heat” can be interpreted as entropy, and the term “entropy” can be used synonymously with everyday “heat”. This interpretation is not common but physically correct and is discussed in detail in Job (1972). The use of “thermal energy” allows the avoidance of the word “heat” in physics instruction (Muckenfuß & Nordmeier, 2006, 2007). Previous studies, which are confounded, however, indicate higher knowledge acquisition with the physical quantities entropy and temperature (Starauschek, 2001, 2002). In our study, we test this hypothesis in an experimental study and, furthermore, take into account the strong and well-known variable of students’ previous knowledge. To summarize the key hypotheses for this study are:

1. The use of the physical quantity entropy leads to higher knowledge acquisition than the use of the quantity thermal energy.
2. Students’ previous knowledge of thermodynamic concepts leads to different levels of knowledge acquisition.

3. METHODS

The hypotheses were tested in an experimental study with two independent variables: the treatment variable “explanations with different physical quantities (entropy/thermal energy)” and the variable “previous knowledge (high/low)”. This leads to a 2x2 factorial design. The sample (N=184) consisting of students aged 14 to 16 years. All students were randomly assigned to one of the two treatments. After conducting a paper-and-pencil pre-test on the students’ knowledge on basic thermodynamic concepts, both treatment groups were additionally divided into the two subgroups according to their level (high or low) of previous knowledge. The content of the cells of the 2x2 factorial design is shown in table 1:

		TREATMENT	
		entropy	thermal energy
PREVIOUS KNOWLEDGE	high	n = 49	n= 51
	low	n= 41	n = 43

Table 1: 2x2 factorial design

The dependent variable “knowledge acquisition” was measured using pre-, post- and follow-up- paper-and-pencil-tests and statistically evaluated using an analysis of variance and analysis of covariance. The measurement instrument of the variable “knowledge” includes 13 field-tested items (Kesidou&Duit, 1993; Starauschek, 2001; Yeo&Zadnik, 2001; Einhaus, 2007). The reliability for this test (α=.646) and the control variables was determined using Chrombach’s Alpha. The following control variables were surveyed with reliable instruments: interest in physics: α=.845 (Fuß, 2006), intrinsic motivation: α=.886 (Fuß, 2006), learning

strategies: α=.649 (Berger &Hänze, 2004), self-concept of ability: α=.892 (Helmke, 1992) and a standardized test on intelligence: α=.798 Heller et al., 2000). Furthermore, the study time was measured. To ensure that no effect results from the repeated-measure-design using the paper-and-pencil-test, one group of students (N=29) participated in the survey as a baseline group without any instruction given by us or by their regular teachers at their school. This group simply completed the pre-, the post- and the follow-up-test within the same timeframe as the other two groups of students, but was not taught in thermodynamics at all during the time of this study.
To prevent confounding by the "teacher" variable, two versions of a computer based learning environment were developed following the multimedia principle (Mayer, 1997). One version uses the physical quantity entropy. The other version uses the physical quantity thermal energy. Each version has a set of seven computer programs covering the basics in the field of thermodynamics for high school students. The individual computer programs consist of about 30 slides. All slides contain hand drawn pictures, audio and written text. The computer program is basically linear structured. At first a picture is shown and the audio is played (figure 1a). After the audio is done playing the student can choose one of the four options by pushing a buttons: (1) Move back to the last slide, (2) listen to the audio again, (3) read the text themselves (figure 1b) or (4) move on to the next slide:

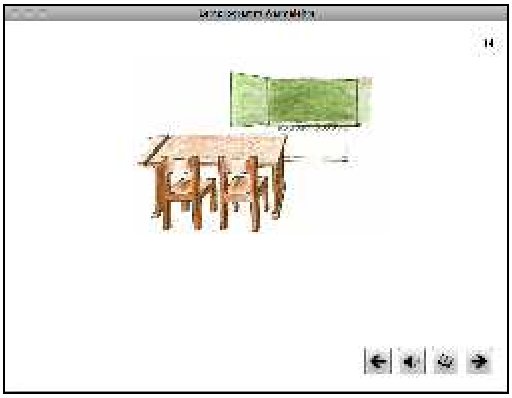

Figure 1a: Slide of the computer program

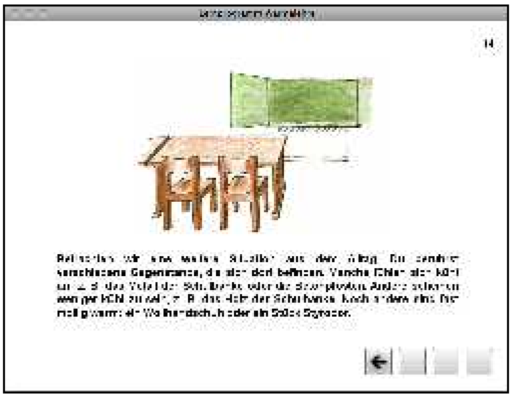

Figure 1b: Same slide of the computer program with the text visible

So even though the slides of the computer program are linear structured individual learning paths are possible. The students can decide how much time to spend on a certain aspect of the topic being taught by listening to audio again or reading the text. Both versions of the computer programs are alike, the pictures are identical, the text and the audio on every slide cover the same content and have almost the same length. The only differences between the two versions are the physical quantities used in the presented explanations. The texts mostly differ only in the names of the physical quantities. An example is given in figure 2a and 2b:

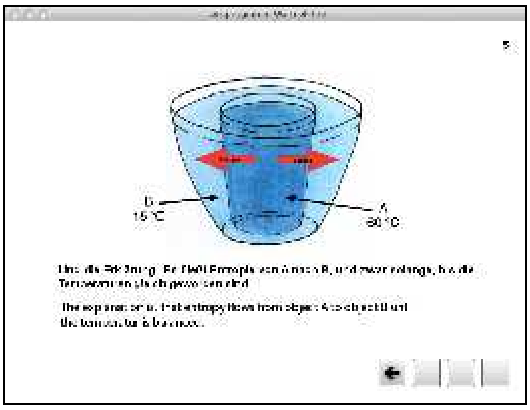

Figure 2a: Version 1 using entropy

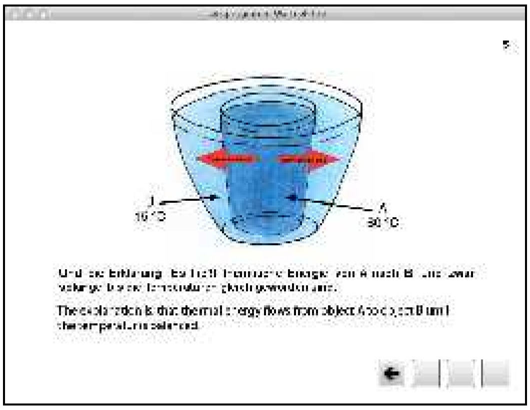

Figure 2b: Version 2 using thermal energy

All students worked separately on their own computer, so that every student could decide how much time to spend with each program. No time limit was given by the instructor. The students worked on three days 90 minutes each using the computer program and doing standardized exercises following each program. More details regarding the design of this study and the computer based learning environment are found in Crossley & Starauschek (2010, 2011).

4. RESULTS

The baseline group did not achieve mentionable knowledge acquisition. The score of the post-test was only slightly higher than the pre-test-score, but the follow-up-test-score was almost identical with the original pre-test-score. All scores did not differ significantly from each other. Therefore the repeated-measure-design seems to have no effect on the students' knowledge acquisition. Moreover, there were no significant differences between the four subgroups of the 2x2 factional design regarding the control variables and no correlation between knowledge acquisition and study time was found (Crossley &Starauschek, 2012 in print).

All four subgroups of the 2x2 factional design had a considerably higher post-test-score.As shown in Figure 3, two main effects were found using analysis of variance: (1) Students learning basic thermodynamics with explanations using the physical quantity entropy have significantly higher knowledge acquisition ($F_{(1, 184)} = 9.932$, $p = .002$, $\eta^2 = .052$) than the other group. (2) Students with high previous knowledge of basic thermodynamic concepts have lower knowledge acquisition than students with low previous knowledge ($F_{(1, 184)} = 8.952$, $p = .003$, $\eta^2 = .047$):

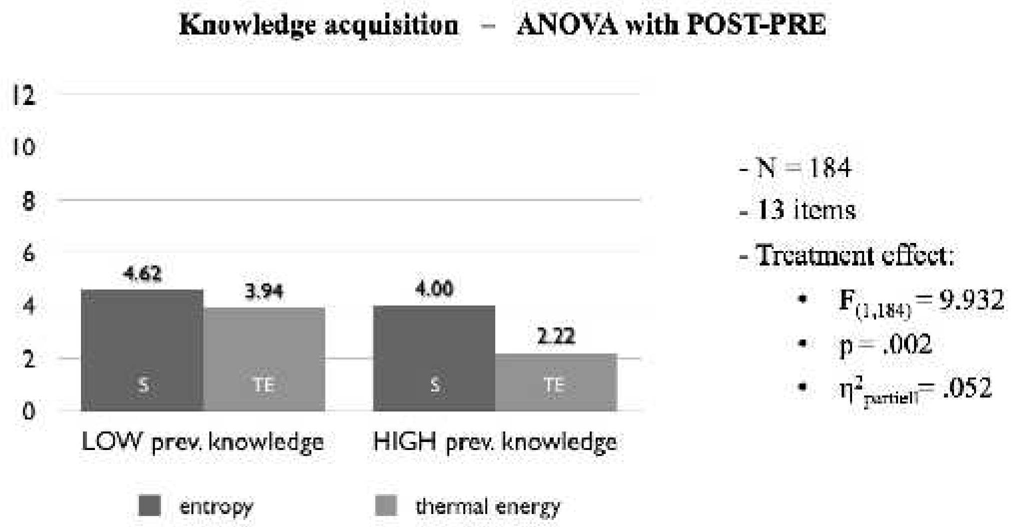

Figure 3: Knowledge acquisition – ANOVA: POST-PRE

It should be noted, however, that because knowledge acquisition was calculated simply by subtracting the pre-test-score from the post-test-score, for students with previous knowledge near the maximum score, it is impossible to have the same absolute gain in improvement as for students with a low level of knowledge.
To verify the stability of this simple method, two other statistical methods to determine the knowledge acquisition were used: (1) An analysis of covariance and (2) an analysis of variance using the hake-factor (Hake, 1998).
The analysis of covariance with the post-test-score as the dependent variable, treatment and previous knowledge as fixed factors and the pre-test-score as the covariate leads to a comparable result ($F_{(1, 184)} = 7.962$, $p = .005$, $\eta^2 = .043$):

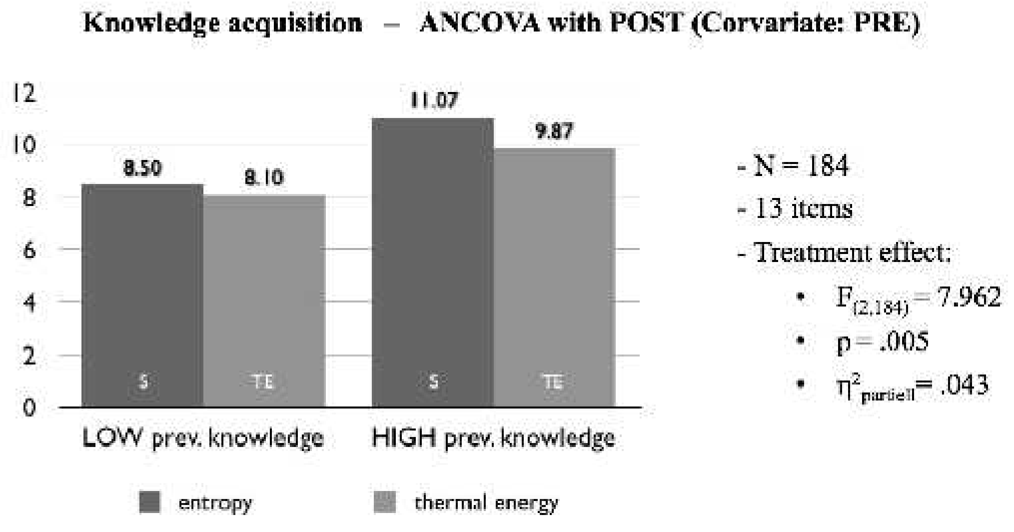

Figure 4: Knowledge acquisition – ANCOVA: POST with PRE as covariate

Again the explanations using the physical quantity entropy lead to significantly higher students' knowledge acquisition. Figure 4 shows that students with a high level of previous knowledge about thermodynamic concepts reach a higher score than students with a low level of previous knowledge. But the gap between these to groups becomes smaller.
Finally knowledge acquisition was determined using the hake-factor (Hake, 1998).When comparing the scores of two tests a person took, the hake-factor takes the maximal possible

knowledge acquisition into account. The data was statistically evaluated using analysis of variance with the hake-factor as the dependent variable and the same fixed factors:

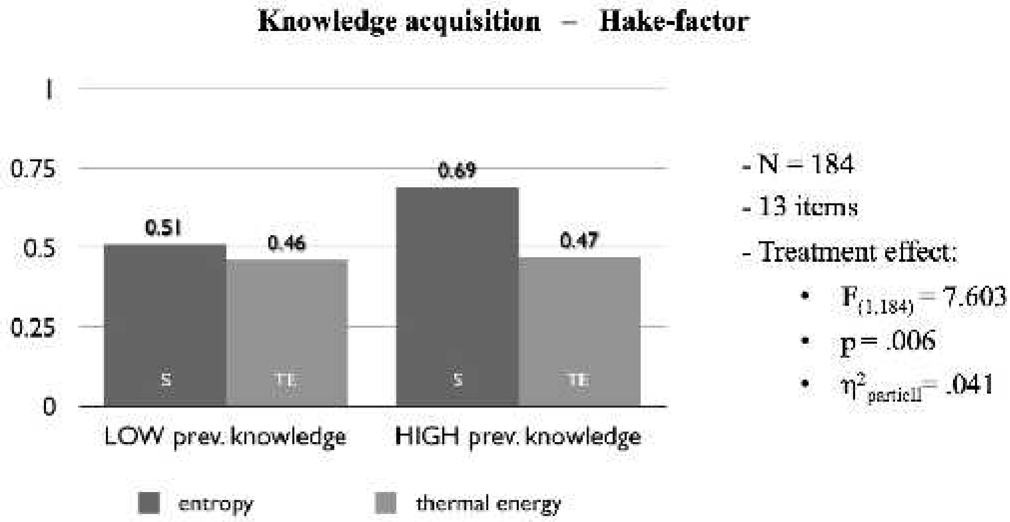

Figure 5: Knowledge acquisition – ANOVA: hake-factor with POST and PRE

The students that had received instructions using the physical quantity entropy reach a significantly higher hake-factor than the other group of students: $F_{(1, 183)} = 7.603$, $p = .006$, $\eta^2 = .041$. Figure 5 also shows that students with high previous knowledge that received instructions using the physical quantity entropy had the highest benefit of all students that participated in this study. The analysis using the follow-up-test results data lead to similar results, simply the effect sizes become a little smaller.

5. CONCLUSIONS AND IMPLICATIONS

The study firstly shows that small variations in the explanations lead to medium effects and can be measured using the experimental design settings described above. Differences between the two student groups result from using two different physical quantities in the teaching environment. It was found that the use of the physical quantity entropy resulted in significantly higher knowledge acquisition than the use of the physical quantity thermal energy. It was also found that the gap between students with a high level of previous knowledge and students with a low level of previous knowledge on thermodynamic concepts becomes smaller for both treatment groups. But students with a high level of previous knowledge that received instructions using the physical quantity entropy had the highest benefit.

The reinterpretation of heat as entropy seems to work well and, in fact, better than the avoidance of the word heat and using thermal energy instead. This study also shows that even a weak intervention can have effects on the learning process that cannot be disregarded.

A SUSTAINABLE TEACHER TRAINING: APPROACHING MORE SCIENCE CONTENT AND INQUIRY

Margareta Enghag[1] and Birgitta Norberg Brorsson[2]

1 Karlstad University
2 Mälardalen University

Abstract: How can teachers change the way they teach so students get access to more features of inquiry based science teaching and learning? Four teacher educators and researchers worked with five teachers from two schools, to develop tools to analyze teaching sequences. The teachers' lessons were video-taped on two occasions at least with several weeks in between. The films were analyzed and various didactic issues discussed in seminars with the researchers and the teachers. After the first lesson feedback, the teachers were given the challenge to make a teaching sequence paying regard to his/her reflections on our seminar and our analysis of the first lesson**.** We report a case study in which a teacher, Roy, develops his teaching in several respects such as dialogic communicative approaches, writing, and science content. We compare and analyze two of his lessons: the first on Electricity and the other on the Water Cycle. The teacher Roy is able to create interesting lessons in which argumentation and debate are included. With the second lesson Roy showed awareness of the significance of the science content in the dialogue, and he gave a greater subject-matter depth compared to the first lesson, as well as a wider variety of scientific ways including experimental work. The science content was, however, superficial and vague in both lessons. The difficulty of meeting the students in dialogue occurs when the teacher's own knowledge is insufficient. The teacher's awareness of the importance of dialogue in the classroom combined with a greater depth of subject focus, lead to learning opportunities for students that are of benefit for both language and science skills.

Keywords: communicative approaches, teachers professional development, dialogic inquiry, inquiry-based science teaching/learning, writing in science

INTRODUCTION

Teacher training in the form of short-time courses or teachers' seminars with lectures have been shown to have limited success concerning the teachers' reception and implementation of new ideas and skills in the classroom, and over time. The research literature concludes that effective teacher training in contrast to the 'one-shot workshops' or 'top-down cascades training' must be characterized by 1) the teachers helping each other with school activities, and 2) an emphasis on self-instruction and opportunities to practice in a context where the teachers are active and choosing their own goals, and 3) training ongoing over a long period of time 4) support, demonstrations and feedback. (Adey, 2004; Schwille, Dembélé & Schubert, 2007)

This paper presents a case study from science teaching in a Swedish compulsory school. Four teacher educators and researchers have cooperated with five teachers from two primary schools, to develop tools to analyze teaching sequences that will be used as material for reflection in new teachers professional development programs (TPDPs). We have an approach of working with teachers as a ‘community of practices’ (Wenger, 2004), into which the researchers bring knowledge from the research community. The teachers bring the contextual knowledge about the class, the background to the teaching situation, the possible level of framing the science content of lesson, limitations and strengths that are present in the actual situation for the teaching and the relation to the curriculum. We focus on one of the teachers, Roy, and the way he consciously varies his teaching towards dialogic communicative approaches including writing, and the way he frames his teaching in aspects of science content. When working with Roy and his colleagues, we showed and referred to domain-specific instructional theories in research literature. By introducing examples from such literature, the teachers got engagement and inspiration to give priority to science content of teaching in the classroom. The ownership of the final design of the teaching–learning is always in the hand of the teacher, which we find obvious, but needs to be expressed and argued for.

AIM AND RESEARCH QUESTIONS

The overarching objective is to build a sustainable teacher training in science by letting schools and researchers work together for a long period of educational development, and through TPDPs introduce inquiry-based science teaching / learning to stimulate students' engagement in science and technology. Another aim is to challenge the teachers to create science-based lesson sequences in science and technology built on increased awareness of communicative and dialogic approaches in their science classes.

In this paper we like to answer the following research questions:

- What researched-based activities did the teacher use in the lessons?
- How is the lesson time spent on different types of activities?
- What types of communicative approaches are used?
- What lesson activities allow dialogue?
- How is writing used as part of the dialogic science discourse?

THEORETICAL BACKGROUND

Our intention to create ‘sustainable’ teacher training, means that we want teachers to get research-based information that help them look upon their classrooms with new eyes. We find it plausible that teachers with a changed view on teaching/learning are themselves able to create a new learning environment in the classroom. Adey (2004, p.169) argues: ‘Successful implementation of innovative teaching methods through professional development requires a combined approach, providing teachers with information, guidance, and leadership while recognising that no outsider can impose a model.’ Our aim is to inspire teachers to develop a dialogic inquiry based science teaching/learning, in this study *guided* inquiry (Guesti,2008). Dialogic inquiry takes departure in the view that fundamental for dialogic classrooms is the students having self-confidence, and there being trust and respect among students, and between students and teachers. Therefore, the feed-back given from teachers and other students is essential. Students with different backgrounds, different languages, and experiences create the classroom environment. Different opinions clash and lead to further development of ideas. A dialogic teaching requires that students can join in a dialogue with the subject matter, which can usefully be made in writing. This special form of dialogue can also be found when students work in small groups and use *exploratory talks* (Barnes & Todd,

1995) to find the answer to a specific question. Episodes that include dialogic inquiry also mean situations when learners and teachers together explore ideas that are not planned for the lesson, but are initiated by the way the dialogue has taken place during the classroom discussion, for example by students self-generated questions.

Mortimer and Scott (2003) developed a model for the scientific conversation in the classroom in their book *Meaning-making in secondary science classrooms*. The teacher's approach to the talks can be studied in the dimensions of interaction / non-interaction and authoritative (mono-logical) / dialogic. With this model, the conversation can be analyzed by using the talk chains built up. The triadic conversation IRE (initiation-response-evaluation) is typical of the monologue / interactive call. The IRE pattern is often built on question- answer-evaluation, when the teachers make the students “que-seekers” the pupils guess the word the teacher is aiming at. This pattern is distinguished from the dialogic interactive IRFRF pattern (initiation-response-feedback-response-feedback), in which students get more space. The IRFRF pattern of discourse can be found when the teacher instead of asking yes/no questions, encourages and prompts the pupil to tell the class of personal ideas around the phenomenon that is in focus. Mortimer and Scott (2003) emphasized that teachers’ awareness of these different approaches could help them vary between different approaches in an appropriate way. They described further on, the teacher’s responsibility to: 1) present the scientific ideas on the social plane, 2) discuss the ideas with the pupils to help them internalize the ideas, and 3) hand the ideas over to the students to make them their own. In our seminars with the teachers we also discussed principles of dialogic teaching based on Alexander (2004).

Writing is a powerful dialogic means and a tool in the learning process, that makes the student sharpen the thinking and in an intelligent manner use appropriate concepts. In the international writing research there are two main directions, both of them dialogic means but in different ways. One direction, *Writing Across the Curriculum* (WAC), stresses writing-to-learn-strategies, which can be used in all subjects. Spontaneous writing and writing to investigate can help the pupils ”make the content of the subject their own”. This kind of writing can be used in various ways in short “mini-writing” tasks such as: What do you know about…? What is your opinion of…? What solution do you think is best? Why? These texts primarily serve as the student’s thinking tool, discussion and dialogue in groups. The other direction, *Writing in the Disciplines* (WID), stresses the terminology of each subject, its linguistic style and requirements of the subject specific genres, for example the lab report in natural science. In this kind of writing the student’s text has a reader, which is more demanding than writing for his/her own thinking.

METHOD

Through presentations in a seminar series on science education, four teacher educators and researchers made contact with primary school teachers, who were interested in participating in individual training with mentor support, to develop science teaching. Two primary schools and five teachers volunteered to join the project. Initially the teachers were interviewed. The teachers’ lessons were video recorded and analyzed. In seminars feedback on the analysis of science content and communicative approaches was given as well as lectures on teaching with a dialogic approach. Oral and written orientation on recent research was given. After the first lesson feedback, the teachers were given the challenge to make a teaching sequence paying regard to his/her reflections on our seminar and our analysis of the first lesson.

The teacher we follow in this case study, Roy, taught two grade 5 classes (students 10 – 11 years of age). In this presentation we analyze and compare two of the lessons in his class: the first introducing electricity/energy, the second dealing with the water cycle. The lessons have been analyzed in terms of activities, science content and writing. We use the structure for a 'design brief' described by Leach, Ametler & Scott (2010) to follow how Roy implemented the teaching sequences leading to the lessons The Water cycle and Electricity.

Description of the context for the designed teaching

The Swedish Curriculum of 1994 (Lgr 94) was in use during the project period (in August 2011 a new curriculum for the Swedish compulsory school was introduced). The purpose of the physics subject, as described in the curriculum, is based on students' desire to know more about themselves and the world. Particular attention should be paid to the teachers actively helping the students achieve understanding. At Roy's school there are many qualified and experienced teachers, but like Roy, some of them lack science in their teacher qualification. The school has a special task to work with students with Swedish as second language, and up to 75 percent of the students come from non-European countries.

The pedagogic strategies and sequencing of content to be used in Roy's teaching are:
Staging the scientific story, Supporting student internalisation, Handing over responsibility to the students and Design tools.

In order to analyse the lesson activities, the videos are categorised (with time as unit of analysis) with the help of computer programs (Videograph, SPSS), and the percentage distribution of class time on 1) teacher's instructions, 2) scientific discussions, 3) problem solving with the investigation, 4) writing tasks and 5) small-group work. Furthermore, Roy's use of different communicative approaches (Mortimer & Scott, 2003) was categorized in a scheme for dialogic inquiry: interactive dialogic, interactive authoritative, non-interactive dialogic and non-interactive authoritative. The scientific content is categorized into concepts, applications, larger context, and socio-scientific issues. Analyses of Writing Across the Curriculum (WAC) and Writing in the Disciplines (WID) were made, as well as oral and written elements of argumentation.

RESULTS

The lesson on electricity, which we video-recorded and discussed in our seminars with the teachers, lacked full clarification of scientific concepts, it contained no experiments, and no writing. The external environment was presented with a video on hydroelectric power and later on also other sources of energy production were discussed. The lesson ended with a value-training task in which the students were asked to vote for which kind of energy supply they preferred: nuclear power, wind-power, waterpower or solar power.

In the following we are focusing on the second lesson, the lesson on The Water Cycle, where we saw many examples on interactive/authoritative talk as in this situation reviewing an earlier lesson:

Roy:	You remember last Friday we started to do a water test. What did we do, Amanda?
S7:	We had four glasses that we filled with water. So we put one on the shelf, one on your table, one below the electric heater and the one under the sofa.
Roy:	Why did we do it? Why do we put a glass of water at different places?
S7:	To check if it had evaporated.

Roy: Evaporated. Let's check what has happened to the four glasses. We talked about some other things about water, too. I'll write down some key words that you should have in mind today, so you remember what they mean.

Now the students are asked to write down everything they know about the water cycle. After five minutes they discuss in groups of 3-4 students and close with a presentation where each group explains what they come up with. The teacher gives a summary of statements as he draws the sun, water waves and arrows on the blackboard:

Roy: We have a sun, which warms. This is a sea (drawing) - it will conduct heat from the sun (draws stretch down from the sun to the water) - it evaporates water from the water surface (arrows are drawn up from the water surface). We have the energy needed to heat the water. It rises. What rises? Do you know what it's alled?
S1, S2: Steam. Water vapour.
Roy: Yes, and it's a gas. What happens to the water vapour, then?
S2: It goes up to the clouds.
Roy: The formation of clouds of gas is up here. Does it start to rain at once?

One of the problems we face in the conversation above, is that the teacher is not aware of the difference between water steam and water droplets. He draws two clouds on the blackboard to illustrate a cloud with 'gas' and a cloud with water-droplets. The conversation starts as interactive/authorative, but gradually becomes interactive/dialogic. The atmosphere in the classroom opens up for student generated questions:

S4: Cool! It's a weird thing I have always wondered about. Why is the snow white?
Roy: Why is the snow white?
S4: Yes, just white.
S1: It may well be yellow too.
Roy: (all laugh) Yes, if somebody has peed on it, yes. I don't know why the snow is white, it's some kind of crystals that reflect, I really do not know. The ice crystals are white.

The lesson continues by checking from which of the glasses the water has evaporated the most, and to write down the results into a template for a laboratory report with the headlines: water cycle, evaporation, condensation, energy. A last brain-storming started by writing in log-books on the question: Will water evaporate at any other places than rivers, lakes and oceans? After the following group discussions the teacher summarizes what the students have come up with:

Roy: It is your breath. It is hot, then it .... water vapour.
S6: In a sauna, it will be like really hot when you blow on himself. . But when one blows here all is just normal.
Roy: Yes. What more needs water to survive then? Do animals evaporate? Is the only place it evaporates from when doing so? (Roy breathes hard.) Amanda, you can see your breath when it's cold outside. (Makes a gesture from the mouth to show the breath). Is it the same thing in here though I do not see it? Is steam coming out? Have you done like this with a mirror? (Blowing against the palm to illustrate). How is it then? (Several students rush to respond). Foggy, misty. What is this?
Roy: Water vapour.

The communicative approach has become even more interactive/dialogic, as student experiences are told and discussed. Unfortunately the same teacher's view on water steam as water droplets make the science content questionable. The lesson concludes with an experiment that is described in the logbook – the evaporation from the hand put into a plastic bag and sealed with a rubber band.

In table 1 the communicative approaches in the two lessons are compared. The intention to enhance the dialogue towards dialogic interaction has been successful with an increase from 40% to 60% between the two sequences.

Table 1: Percentage distribution of time for different communicative approaches

Lesson	Interactive/ authoritative	Interactive/ dialogic	Non-interactive/ authoritative	Non-interactive/ dialogic
Electricity/Energy	47%	40%	11%	1%
The Water Cycle	16%	60%	23%	0

In table 2 is shown how the natural science content is distributed quite differently between Roy's first and second lesson.

Table 2: Percentage distribution of time for the science content divided into categories

Lesson	Concepts	Application / Natural Phenomena	Wider context	Socioscientific issues
Electricity/Energy	4%	51%	37%	9%
TheWater Cycle	92%	7%	1%	0

Analysing the kind of science content focused in the lessons, we see in table 2 four categories. The science concept part has increased considerably in the lesson that was inspired by dialogic teaching, but all broader contexts have a remarkable decrease.

In table 3 below is shown how Roy used writing as a dialogic learning tool in his science classroom.

Table 3. The use of writing in Roy's classroom

	Lesson I Electricity/Eenergy	**Lesson II Water Cycle**
Writing as a thinking tool and a basis for discussion	no	yes
Writing of specific genres	no	yes
Reporting facts in full sentences	no	yes
Reporting a course of events	no	yes
Arguments supported by facts reported in full sentences	no	yes
Use of specific concepts	no	yes

As can be seen in table 3 there is a big difference as to the use of writing between the two lessons. In lesson I no writing tasks were given at all, while it was an important element in the lesson on the Water Cycle. Roy used writing as a tool for thinking and as preparation for group and whole class discussions, which made the students feel safe and free to express themselves. He also used writing in the lab reports – a very specific genre of natural science, which the students must gradually learn to master.

DISCUSSION AND CONCLUSIONS

During this collaborative project more dialogic elements were included in the lessons in which student questions were discussed and the content problemised. The students were given greater autonomy to express their thoughts, and to participate in a dialogical conversation, both oral and written, with each other and with the teacher. The academic language of natural science was focused, and the students got greater opportunity to expand the vocabulary of scientific concepts. The teacher increased the amount of interactive dialogic conversation, and used inquiry and experiments in several lessons following on each other. The teacher had, by adopting the theoretical frameworks afforded, changed his view on dialogic aspects in the classroom, and on the importance of language for students to become disciplinary discourse participants. New words and concepts are provided to the students by talking and writing exercises – and emphasise is on letting the students express their own ideas and questions. Experiments were planned and guided inquiry gave high engagement among the students. A sign of learning is the relevant questions, which could be seen also in the writing tasks.

In this case study the collaboration between teachers and researchers is built on the teachers' ownership of the teaching content, which is allowed to vary widely. Focus on learning objectives and subject content is strong. The teachers' awareness of their own communicative approaches, of the science content being varied between concepts, applications and broader contexts, and of science writing as a dialogic means, are other important factors. The students had to use the new concepts of the water cycle in several ways, in listening, in writing, in oral, and also by drawing in their lab reports. Consequently, Roy's use of writing as a dialogic and learning tool connects to both the WAC and WID research directions. By varied linguistic use the students strengthened their knowledge.

The teacher Roy is able to create interesting lessons, where argument and debate are included. The science content, however, was in the first lesson superficial and vague. With the lesson on the Water Cycle the teacher showed awareness of the significance of subject content. He was able to give a greater depth and more variety of scientific ways of working and experimental moments. The difficulty of meeting the students in dialogue occurs when the teacher's own knowledge is insufficient. However, Roy, who is not formed by the science education 'canon', has much to teach us about science teaching in risk of becoming too narrow. We are convinced that this teacher has new tools to work with in designing new lessons, and an interest to enhance his own science understanding, with the positive response his students gave him.

We see a great need for more subject knowledge, which cannot be met by simply increasing awareness and use of our tool for analysis of educational content. With the teacher's' experience of dialogue in the classroom and a greater depth of subject content, rich opportunities for students' learning that benefit both the language and science skills would be created. We maintain that the training model described above has the potential to support teachers' learning. A TPDP needs to provide meaningful learning that takes into account the aspects discussed. There is evidence in the literature that the model we are developing together with the teachers delivers the key components necessary for an effective teacher training that leads to teachers learning. We believe that by not only disseminating teaching ideas, but also participating, and by supporting the individual teacher and the team during the implementation and development of ideas in the teacher's own learning environment, we help the teachers to revitalization and increased motivation.

Abstract: Learning astronomy is challenging at all levels due to the highly specialized form of communication used to share knowledge. When taking astronomy courses at different levels at university, learners are exposed to a variety of representations that are intended to help them learn about the structure and complexity of the Universe. However, not much is known about the reflective awareness that these representations evoke. Using a simulation video that provides a vivid virtual journey through our Milky Way galaxy, the nature of this awareness is captured and categorised for an array of learners (benchmark by results obtained for experts). The results illustrate how the number and nature of new things grounded in *dimensionality, scale, time and perspective* reflective awareness can too easily be taken for granted by both teachers and learners.

Keywords: Astronomy Education Research, Perspective, Awareness, Representations

Introduction

Learning astronomy can be difficult for learners at all levels due to the highly specialized form of communication used to share knowledge in the disciplinary discourse of astronomy. The learners' can be anyone interested in learning astronomy, from amateurs to astronomy and physics graduate students. When taking astronomy courses at different levels at university, learners are exposed to a variety of *representations* with the aim of helping them learn about the Universe. Many of these representations have been created in two-dimensional form (2D) and experts (teachers who are professional astronomers or physicists) involved in this case study wanted the learners in their classes, to come to understand, or better understand, some of the more fundamental processes and underlying structures of the Universe from those representations.

Teachers often take for granted that learners experience, and develop, a three dimensional (3D) representation of the Universe in their minds, i.e., this is an aspect that is often *appresent* to the learners. For example, when teachers introduce nebulas using 2D pictorial representations and 3D verbal representations a visual appresentation aspect is introduced. Such appresentation aspects are further enhanced when time, as the forth dimension, is introduced.

Simulation videos are often used to dynamically introduce learners to the structure and complexity of the Universe in 3D. However, little is known about the learning possibilities that such a collection of representations (representation affordance), may present to reflective learners (cf. Schön, 1991).

Our case study was designed to initiate an investigation into the nature of this awareness. Our starting point has been to use a highly regarded and widely used simulation video that sets out to illustrate some of the fundamental structural components of our Universe by taking viewers on a virtual reality journey through and out of our Milky Way Galaxy. Results in terms of evoked awareness for groups of undergraduates and experts' are described and discussed.

Research setting

There is a growing international interest in viewing learning, in areas such as physics and astronomy, from a disciplinary discourse perspective. Such a perspective suggests that challenges to learning may be related to difficulties embedded in the handling of the highly specialized forms of communication used to share knowledge within a discipline (for epistemic examples, see Driver & Ericksson, 1983; Säljö, 2000; and diSessa & Sherin, 2000). Our study is hence built around a disciplinary discourse modelling of how both teachers and learners work with this communication (Airey & Linder, 2009) using a particular example of a simulation video that is widely used to dynamically introduce learners to the structure and complexity of the Universe in 3D (*Flight to the Virgo Cluster* which can be found at http://www.ifa.hawaii.edu/~tully/outreach/movie.html). This video introduces a viewer to the Milky Way in colour and three-dimensional orientation across millions of light years of simulated travel across the Milky Way. The research agenda sought to capture the reflective awareness of fundamental structural components of our Universe that was afforded to viewers as they engaged with the first million light years of the video journey.

Research question

What is the nature of awareness afforded by the disciplinary representations encounted in a computer simulation of travelling through the Milky Way Galaxy?

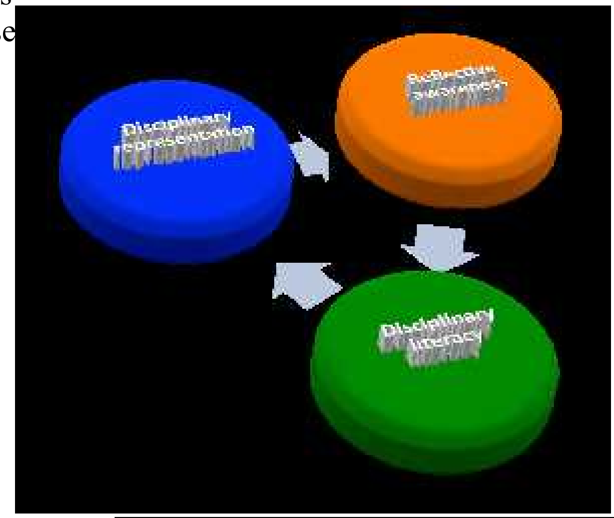
Theoretical framework

The research framing draws on the Airey & Linder (2009) modelling of disciplinary discourse in relation to semiotic representations and on Schön's (e.g., 1991) development of John Dewey's formulation of reflection in a learning situation.

Airey & Linder (2009, p. 28), using a multimodal lens (cf. Kress et al., 2001), defined disciplinary discourse as "the complex of representations, tools and activities of a discipline". They use their modeling of disciplinary discourse and the related learning possibilities of different disciplinary representations to develop a "generative metaphor" (Schön & Argyris, 1978) of *discursive fluency*: "By discursive fluency we mean a process through which handling a mode of disciplinary discourse with respect to a given disciplinary way of knowing in a given context becomes unproblematic, almost second-nature. Thus, in our characterization, if a person is said to be discursively fluent in a particular mode, then they come to understand the ways in which the discipline generally uses that mode when representing a particular way of knowing" (Airey & Linder, 2009, p. 33).

For a learner to become discursively fluent in introductory parts of the disciplinary discourse of astronomy, we argue that the concepts needed are those we illustrate in Figure 1:

- **Disciplinary representation:** the collection of disciplinary representations that makes up the 'disciplinary discourse' that enables disciplinary knowledge sharing.
- **Disciplinary literacy**: the ability to appropriately participate in the communicative practices of a discipline (Airey, 2011a; 2011b).
- **Reflective awareness**: the learning affordances that engagement with a collection of representations facilitates. The notion of reflection here is drawn from the work of Schön (for example, 1983) in that it is related to our learning experience and the noticing of new things and the noticing of things in new ways.



[redacted]

Recent reviews of astronomy education research show that almost all of the work done in this field has taken place at a pre-university level and that very little has been grounded in a disciplinary discourse perspective (Lelliott, 2010; Bailey, 2011). The work reported on in this paper goes towards addressing both shortcomings. It attempts to provide further understanding of the astronomy learning experience.

Method

From a pilot study, conducted on a small group of nine physics learners and one astrophysicist expert, we obtained reflective descriptions showing how learners and experts differed in how they chose to describe what they noticed when viewing the Flight to the Virgo Cluster simulation. The learners descriptions lead to fewer and characteristically less sophisticated categories (e.g. description of the Milky Way, relative distances between stars, nebulas and galaxies) whereas the experts' descriptions, besides being characteristically more sophisticated (e.g. shape and colour of nebulas, the 3D representation of the video versus elapsed time, stars and exoplanets, gravity and the shape of the galaxy), were also larger in number.

A survey was undertaken and made accessible on the web through the online survey: *Awareness of the Universe* at www.hkr.se/AER (Username: galaxy, no Password). The data obtained for the case study reported on at the time of the ESERA 2011 conference was collected from some 34 participants from universities in both Sweden and the USA: 23 learners form across the Swedish university spectrum (Introductory astronomy, Astrobiology, Second year undergraduate physics learners, and Ph.D. students), and 11 experts from both Swedish and US university settings.

The participants were shown video clips extracted from the Flight to the Virgo Cluster simulation and where asked to reflect on what they had seen by answering the following questions:

Watch this clip and answer the questions below! Please answer the questions in order of appearance, using numbers. If you have not noticed something new, feel free to say so.

1) Please write what comes to mind when you watch this clip, like things you noticed, sudden new realizations or connections, surprising or confusing things.

2) What, if any, "I wonder..." questions did this clip raise for you?

The video clips were obtained by clipping a piece of the video into seven short logically holistic sections, lasting on average 15 seconds, and stopping the video at these points to allow for the participants to write down aspects of their reflective awareness which were related to each video clip (just watched).

After the seven clips were viewed and the accompanying questions answered, five follow up questions were asked so as to ascertain, for example, whether they knew where the journey started/ended and things what particularly caught their attention in the movie as a whole.

These written reflective descriptions were coded and sorted into constructed categories, using a constant comparison approach (Strauss and Corbin, 1998; Gibbs, 2002). In other words, the categories were not pre-defined, but rather emerged from the data.

Results and discussion

The analysis of the on-line survey showed that learners' reflective descriptions were markedly different from those of the experts. In terms of the nature of awareness associated with the array of representations that made up the clips of video used for the study, shape, colour and 3-dimensionality were the most prominent in the constituting of conceptualizations in the reflective descriptions. In particular, the representations embedded in 3D generated a clear dimension of "noticing things in new ways", which collectively we characterized as "progressive layers of discernment". When comparing and contrasting learners and experts the profile of awareness categories differed as follows:

Learners: Orion, constellation, perspective, 3D, scale, gas blobs, nebulae, galaxy, colours, speed, structure, the Milky Way, etc.

Experts: Orion, constellation, perspective, 3D, scale, emission nebulae, reflection nebulae, absorption nebulae, stellar nurseries, time, speed, the Milky Way, other galaxies, distribution of stars, stars, star formation, stellar evolution, exoplanets, gravity, star clusters, excitation and de-excitation, HI and HII regions, parallax, etc.

These results are summarized in graphical form in **Figure 2** in terms of learner academic level and the average number of awareness categories that were identified in the video answers provided by the participants.

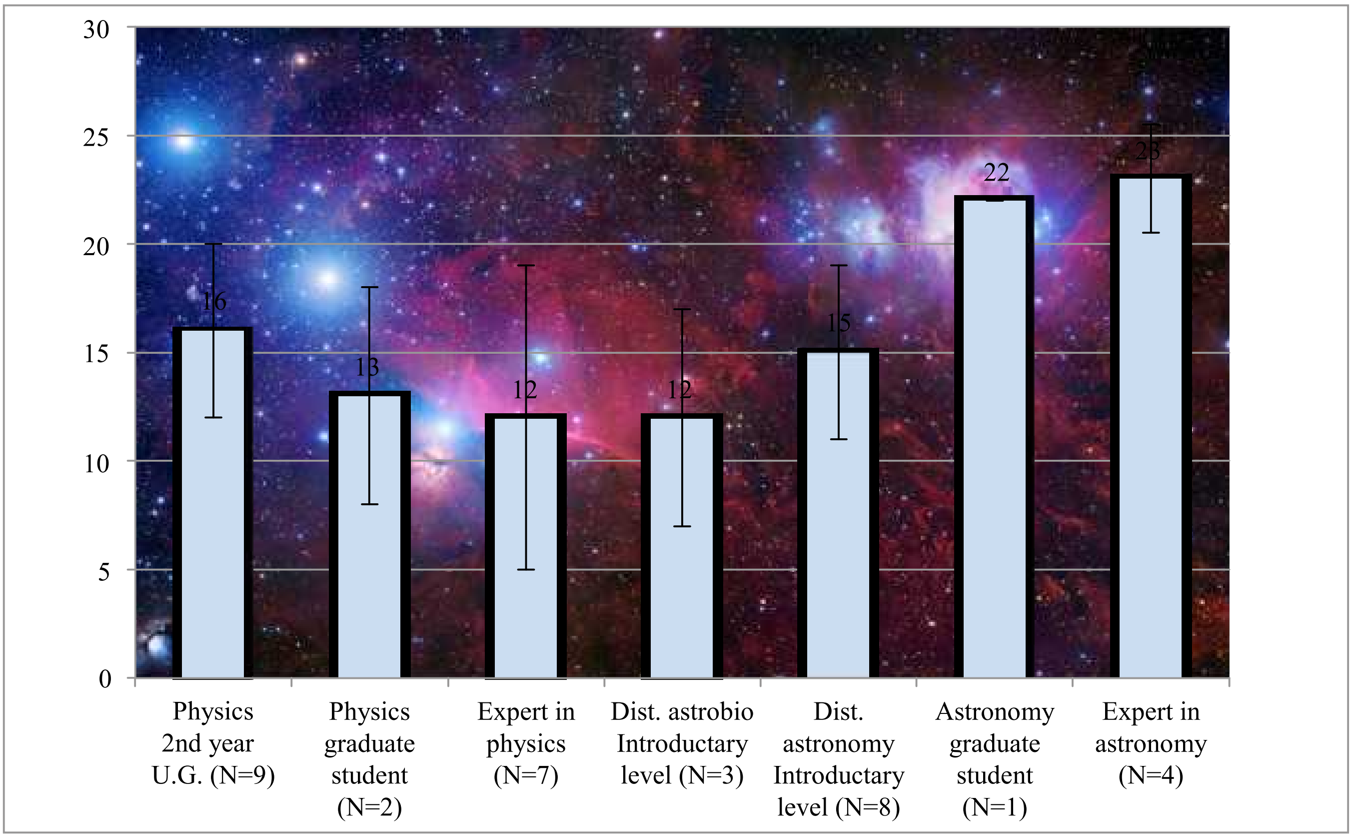


Figure 2 The preliminary results from the study, where the different groups of learners' are plotted on the horizontal axis in academic progression order/subject versus the number of used categories on the vertical axis. The heights of the bars are the average number of categories that we have identified for each group with N=x participants. The error bars are the standard deviations, or, if the number of participants in a group is too low it is the actual spread.

There were also clearly discernable differences between learners from the astrobiology course and learners from the astronomy course. The astrobiology-course learners awareness was grounded much more in esoteric descriptive items such as exoplanets, search for extra terrestrial life, space travel, and shining fog. On the other hand, the astronomy-course learners profile was very similar to that of their general physics counterparts in terms of the number of awareness categories that they used in their descriptions. However, the actual categories did not overlap nearly as well. The physics learners tended to use categories common to a more general physics realm, such as gravity, force, emission lines from different elements (H and He), and the colours of nebulae emanating from different elements and different atomic levels and transitions.

Perhaps the most intriguing result is that across all categories of learners the following categories of awareness were common:

- The experience of 3D -- new *2D-3D awareness*
  Many learners have not experienced the universe as a 3D space; they rather see the Universe in 2D terms, but the simulation gave them insight into the real structure of the universe.
- New *perspective awareness*
  The learners are surprised by the experience of the awareness of new perspectives. For example, noticing how the individual stars in the Orion constellation are at quite different distances from Earth, or seeing a structural view of Orion close up and then passing through.

- The enormous distances between stars and other structures in the galaxy -- the New *scale awareness*
  The learners' answers revealed the difficulties that they had had in appreciating the enormous distances between structures and components of the universe, such as stars, nebulae, star clusters and galaxies.
- New *Time awareness*
  This is an awareness that many learners struggle with in the sense that they do not realise that the Universe they see from Earth does not necessarily look anything like the Universe seen from other places. Because of the limitations that the speed of light introduces to the visual appearance of moving objects, the "actual Universe" is different from what one is able to see from Earth. However, in the simulation, the speed of travel is not related to the passing of time. The learners do not recognise this as being problematic, but they do appreciate that such a journey would take a very long time to actually undertake. On the other hand, the experts often pointed out that the video-presented journey would take too long for it to be possible for a person to experience in real life, and also that time affects the way the universe gets seen.

Conclusions and Implications

Our study is situated in astronomy education research and focuses mainly on the awareness challenges university level astronomy learners' face when trying to create an appropriate visualization of the Universe – that is, in becoming focally aware of the fundamental components, structure, and interactive dynamics of our Universe. By using a realistic video, presenting the Milky Way through a virtual journey, the learners' are given a realistic opportunity to build a 3D, or even 4D (3D + time) picture of the Universe in their minds.

The number of new things that learners need to be able to bring into focal awareness from simulations that deals with properties, structures and interaction dynamics are enormous. To attain an appropriately appreciative understanding means learning to see new things and how to work with them in the context of a given observation. In doing the data analysis we saw how learners may quickly attain new awareness that underpins a deeper understanding of the structure and components of the Universe. This is an indication of the nature of representation affordance that can be evoked by a good simulation, such as the one used in our study, and how important it is for teachers to better understand this learning experience.

Acknowledgement

We thank the following for making this paper possible: the ESERA scientific community; The Swedish Research Council and Kristianstad University, for their funding; Anne Linder, Uppsala University, for her help with the preparation of this paper; and, Professor Brent Tully, Hawaii for kindly allowing us to use the Flight to the Virgo Cluster video for the study.

THE EFFECTS OF AIM-GAPPED EXPERIMENTATION on CONCEPT LEARNING AND GAINING SCIENTIFIC PROCESS SKILLS

İlknur Güven[1] and Ayla Gürdal[2]

[1]*Marmara University, Istanbul,TURKEY*
[2]*Marmara University,İstanbul,TURKEY*

Abstract: This study was conducted to see the effects of aim-gapped experimentation on concept learning and gaining scientific process skills for middle school students. Aim-gapped experimentation is a new experiment technique, which keeps the curiosity alive in students, contributes to meaningful learning instead of just verifying a scientific truth and can be done in a short time (Güven & Gürdal, 2010). The new experiment technique that is "aim-gapped experimentation" is built on ideas derived from information-gap theory (Lowenstein, 1994; cited in Dijk & Zeelenberg, 2007). In this study, Aim-gapped experimentation is defined and the effects of the aim-gapped experimentation to the concept learning and scientific process skills of 7th grade students in "Light Unit" is tested. At the end of the research, teaching with aim-gapped experimentation was found to be a technique having a positive effect on concept learning and gaining scientific process skills.

Keywords: Aim-gapped experimentation, information-gap theory, science education

INTRODUCTION

As an effective method for over a century laboratory had been given a central and distinctive role in science education (Hofstein & Lunetta, 2003). The role of laboratory is to be a bridge between the intangible world of ideas and thoughts and the concrete world of physical reality (Jone & Lewis, 1978, p:4-5). Pratical work- activities in which the students manipulate and observe real objects and materials is often seen by teachers and others (particularly scientists) as central to the appeal and effectiveness of science education (Abraham & Millar, 2008). The effectiveness of the practical work as a teaching and learning method in school science is being critized in literature (Abraham & Millar, 2008; Hoffstein, 1988). Laboratory activities are categorized variously. The type of categorization as "open ended" and "expository" which is very common in literature is done according to the problem, procedure and outcome of the experiment are given or not (Millar, Marechal&Tiberghien, 1999, p.35). In expository experiments students follow given instructions, and the outcome is predetermined. In open-ended experiments the problem may have multiple solutions, procedure is student generated and the outcome is undetermined. In literature "cook book type" experiments are questioned in terms of the meaningful learning (Hofstein, 1988). Aim-gapped experimentation is defined by Güven & Gürdal (2010) and is built on ideas derived from information-gap theory (Lowenstein, 1994; cited in Dijk & Zeelenberg, 2007). Loewenstein defines "curiosity" as "the desire to know." Loewenstein's "information-gap theory views curiosity as resulting from a gap in one's knowledge". Loewenstein, argued that situational determinants may intensify curiosity and curiosity may be positively related to the knowledge we already have. According to Loewenstein the more we know, the more curious we are about what we do not know (Güven & Gürdal, 2010). Aim-gapped experimentation technique is based on the idea of that curiosity leads to better learning (Engel, 2006). In aim-gapped experimentation there are some gaps in laboratory sheets. These gaps make the students curious about the experiment which they will perform. Aim-gapped experimentation makes use of both open-ended and expository experimentation techniques. In aim-gapped experimentation technique, experiment name and procedure are given as in the case of expository experiments; on the other hand, students are expected to find the outcome themselves as in the case of open-ended experiments. (Güven & Gürdal, 2010). Aim-gapped experimentation technique corresponds with information-gap theory. Everything about experiment is not given, an unknown part is being, but some knowledge (exp: procedure) about experiment is given. By that, a gap (aim and outcome) is formed and the curiosity of student is strived to be high. In aim-gapped experimentation experiment sheets are given before they perform laboratory. These sheets are different from expository experiments' sheets. In these sheets the name of the experiment is given as having no clue about the aim of the experiment. The aim of the experiment is not written in the sheet. There is a gap in here. The sheet has procedure and some router questions. At the end of the sheet there is a gap and asks the outcome of the experiment. After writing the outcome students asked to estimate the aim of the experiment and write it to the gap in the sheet.

If the three experiment techniques (expository, open-ended and aim-gapped) are explained on behalf of information-gap theory the result is like that: There is information but not gap, in expository experiment technique. In open-ended experiment technique there is much more gap according to information. In aim-gapped experimentation technique there is much more information according to gap (Güven & Gürdal, 2010). This relation is given in table below:

Table 1:Experiment techniques with respect to information-gap theory

EXPERIMENT TECHNIQUES	INFORMATION	GAP
Expository experiments	▪ Apparatus ▪ Name of the experiment ▪ Aim of the experiment ▪ Procedure ▪ Outcome of the experiment	
Aim-gapped experiments	▪ Apparatus ▪ Name of the experiment ▪ Procedure ▪ Router questions ▪ Tables for data collection	▪ Aim of the experiment (problem) ▪ Outcome of the experiment
Open-ended experiments	▪ Apparatus ▪ Problem	▪ Name of the experiment ▪ Procedure ▪ Outcome of the experiment

As seen on table above, everything is given in expository experiments. In open ended experiments, the rate of information according to gap is very small. For aim-gapped experiments, the rate of given information acoording to gap is bigger (Güven & Gürdal, 2010).

PURPOSE OF THE STUDY

The purpose of this study was to test the effectiveness of aim-gapped experimentation on concept learning and gaining of scientific process skills. The main research question of this study is "Is there any significant effect of teaching 7th grade "Light Unit" in lessons in Turkey which are planned with aim-gapped experiments on concept learning and gaining scientific process skills?".

METHOD

This study was carried out by using experimental design, consisting of pre-test and post-test including a control group. The sample of the study is composed of totally 76 students from an elementary school in Istanbul, in the second semester of 2006-2007 education year. Participants of the study were 7th grade students from two different classes. The same teacher taught the science and technology lessons in the two classes.

In the control group, lessons were planned by the teacher according to the student expectations of 7th grade “Light Unit” of 2005 Science and Technology Program (TTKB, 2006). The teacher did the lessons with rich methods and techniques, as it should be according to the “2005 Science and Technology Program” requirements. For that he used many different methods in addition to experiments like; observation, question-answer, direct explaining method, taking notes, student book activities, visual materials, problem solving, analogy, role play, brainstorming, models, examples from daily life, watching video and homeworks. In the control group students did expository experiments. The sheets of the experiments were given them in the textbook.

The lessons for “Light Unit” in the 7th grade 2005 Science and Technology Program were replanned for the experimental group. The experiments for the “Light Unit” in the 7th grade science and technology textbook which were done in the control group were reprepared according to “aim-gapped experimentation technique”. This technique is differing from expository laboratory experiments, in that the students were not given the aim and the outcome of the experiment. The sheets were given to the students before the lessons. This group of students were divided into 2-3 students groups and all groups did the experiments by following the new experiment sheets. Students were made to write laboratory reports at the end of the experiments. In this group just the experiments were done differently, the rich teaching methods were also used as in the case of the control group. The importance of doing experiments with small groups, writing individual laboratory reports and making the curiosity of students alive were considered in the experimental group. To make the curiosity alive, aim-gapped experiments were used. Aim-gapped experiments are welded from the researcher’s master thesis in which she introduced the “experiments that the aims are not given” (Güven, 2001). Researcher presented the results of the effects of “experiments that the aims are not given” on student success first in the “88th Canadian Chemistry Conference and Exhibition” in Canada (Güven & Gürdal, 2005). Aim-gapped experimentation is built on ideas derived from information-gap theory (Lowenstein, 1994; cited in Dijk & Zeelenberg, 2007). Aim-gapped experiments are formed by mixing the expository and open-ended experiment methods (Güven & Gürdal, 2010). In this research, totally nine experiments were done by the students. The experiment sheets were given to the students like the case in expository experiments. For these experiments’ which were done in the control group new experiment sheets were prepared. In these sheets some gaps were formed just like the case in open-ended experiments. In the experiment sheets the aim of the experiment was not given. The experiments were same as the control groups’ but in the experimental group the names of the experiments were defined again that included no clue about the aim of the experiment. The procedure was given but the outcome of the experiment was not given with the experiment sheets. There were a few router questions in the sheets to make the students write the observations and the results of the experiments. At the end of the experiment, students were made to write the aim of the experiment and for evaluation they wrote experiment reports.

Instrument and Data Analysis

The researcher aimed to test the effectiveness of the “aim-gapped experimentation technique” in the light of the concept learning and gaining scientific process skills. “Open-ended

Questions" (OEQ) and "Problem-Hypotesis Determination Test" (PHDT) were used to determine the students' level of gaining the scientific process skills. OEQ is composed of 8 questions. These questions were prepared by the researcher, taking into account the unit and the target concepts. The content validity of OEQ was based on an expert opinion and 2 science and technology teachers. After the application of OEQ students answers are marked and the points divided into 3 levels: 1st level: Students did not give any answer or had misconceptions in answer (did not comprehended); 2nd level: Students answers were partly correct. There are some missing concepts (comprehended but there are missing concepts);3rd level : Students answers are correct. (Comprehended).

It was aimed to determine the scientific process skills of students to what extent they could gain. Instead of focusing on all scientific process skills "the problem identification", "hypothesis-building" and "identifying the variables (dependent and independent)" (Aktamıs and Ergin, 2007) skills were tested. "Problem-Hypotesis Determination Test" (PHDT) was created in order to measure the skills with 4 different questions. The content validity of PHDT was based on an expert opinion and 2 science and technology teachers. After the application of PHDT students answers are marked out of 100 points (25 points for each question) and the points divided into 3 levels for problem determination and hypotesis building and 2 levels for variables identification. Problem determination: 1-2 points (did'nt comprehend) 3-5 points (partly compreheded) 6-7 points comprehended; hypotesis building: 1-2 points (did'nt comprehend) 3-5 points (partly compreheded) 6-7 points comprehended; independent variable identification: 1-3 points (did'nt comprehend) and 4-6 points comprehended; dependent variable identification: 1-3 points (did'nt comprehend) and 4-6 points comprehended.

OEQ and PHDT were applied to both groups (control and experimental) as pre-test before the instruction and as post-test after the instruction. To compare the results of post-tests of control group and experimental group independent variable "t" test was conducted with SPSS 11.0 program.

RESULTS

OEQ was applied before and after the implementation as pretest and posttest. After the detailed analysis of pretests of both groups answers' it was seen that both groups answers were incorrect; so it was concluded that both groups' students had not enough pre information about the unit of "Light". The data obtained from the post tests was assessed by using SPSS program. Analysis of the quantitative data is given in the table below.

Table 2: Post-test Results of OEQ

Question number	*Group*	*Test*	*N*	*Mean*	*SD*	**Independent Samples t-test**		
						df	t	P
1st question	Control Group	Post-test	36	4,00	3,69	74	-3,22	<0,01
	Experimental Group		40	6,73	3,67			
2nd question	Control Group	Post-test	36	5,44	3,03	74	0,019	<0,05
	Experimental Group		40	7,55	4,42			
3rd question	Control Group	Post-test	36	2,03	2,72	74	-3,86	<0,01
	Experimental Group		40	5,58	4,87			
4th question	Control Group	Post-test	36	4,50	3,96	74	-0,326	0,597

	Experimental Group		40	5,02	4,59			
5th question	Control Group	Post-test	36	2,69	2,81	74	-2,40	<0,05
	Experimental Group		40	4,30	3,00			
6th question	Control Group	Post-test	36	7,17	3,91	74	-2,86	<0,01
	Experimental Group		40	10,03	3,12			
7th question	Control Group	Post-test	36	2,61	3,23	74	-3,51	<0,01
	Experimental Group		40	5,78	4,46			

Independent t-test was conducted to see if there was a significant difference between the post-test scores of OEQ of the control and experimental groups. According to these results there are statistically significant differences on behalf of the experimental group in 1^{st}, 2^{nd}, 3^{rd}, 5^{th},6^{th}, and 7^{th} questions. In the 4^{th} question there is no significant difference between the post-test scores of OEQ of the control and experimental groups. The results of post test scores of 8^{th} question for both groups were almost equal. So, independent samples t-test were not carried out for this question. The results of OEQ are more likely on behalf of the experimental group. In six out of eight questions experimental group did well according to the control group. This means that doing aim-gapped experiments with small groups has a significantly important effect on concept learning.

The results of the evaluation of the PHDT for the successes of "problem determination", "hypothesis determination", "dependent variable determination" and "independent variable determination" are visualized with graphics in below:

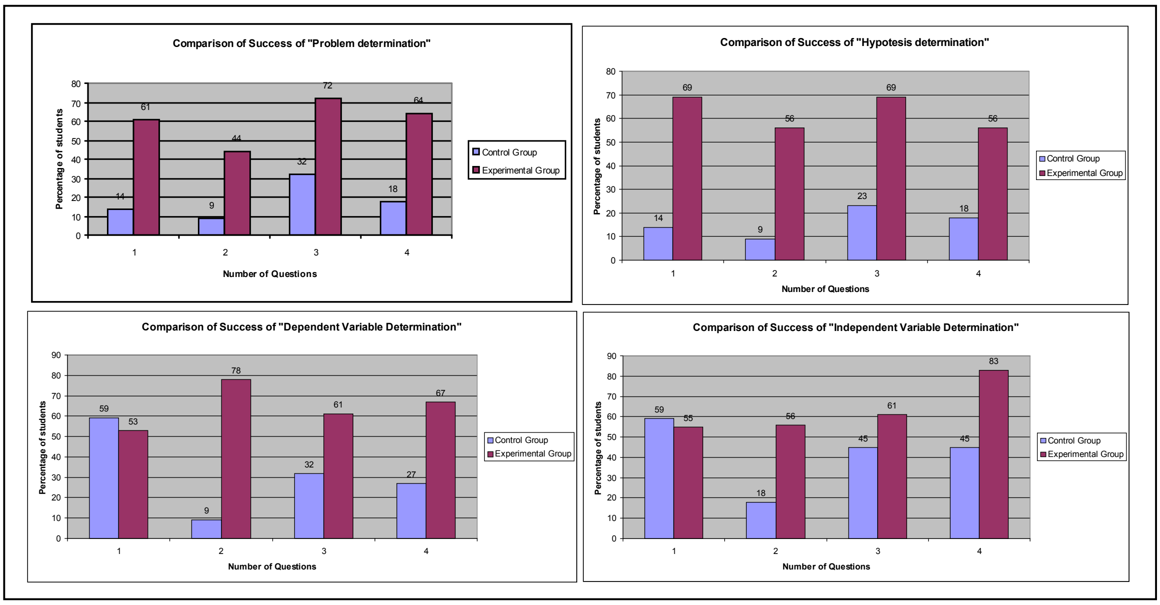

Figure 1: Comparison of percentages of problem, hypotesis, dependent and independent variables determination scores of control and experimental groups

According to the comparison of percentages of problem, hypotesis, dependent and independent variables determination scores of control and experimental groups it can be concluded that the gaining level of scientific process skills of experimental group is statistically different from the control groups'. The students in experimental group were better in determining the scientific processes.

Table 3: Post-test Results of PHVDT

Question number	*Group*	*Test*	*N*	*Mean*	*SD*	Independent Samples t-test		
						df	t	P
1st question	Control Group	Post-test	31	9,13	6,71	65	-3,02	<0,01
	Experimental Group		36	15,64	7,74			
2nd question	Control Group	Post-test	31	6,19	5,73	65	-5,73	<0,01
	Experimental Group		36	16,58	8,58			
3rd question	Control Group	Post-test	31	9,00	7,71	65	-3,56	<0,01
	Experimental Group		36	16,64	9,57			
4th question	Control Group	Post-test	31	6,71	9,26	65	-4,76	<0,01
	Experimental Group		36	17,31	8,94			

To compare the results of post-tests' means bof control group and experimental group for PHDT independent variable "t" test was conducted with SPSS 11.0 program. According to the results it can be seen that the gaining level of scientific process skills of experimental group is statistically different from the control groups'. The students in experimental group were better in determining the scientific processes.

CONCLUSION AND IMPLICATIONS

In literature cook-book type experiments were criticized (Hoffstein, 1988) and science educators draw attention to the importance of seeking new trials (Anders at all, 2003). In this study it is tried to give a respond to the need of alternative laboratory techniques. For that, aim-gapped experiments were performed by small groups and students wrote experiment reports for evaluation. At the end of the study it was seen that aim-gapped experimentation has positive effects on concept learning and teaching scientific process skills. In aim-gapped experiments students learn through the process not just through the results (Güven & Gürdal, 2010). Thus, the experiment sheets which were given to students before the experiments were informational sheets with some gaps in them and they were not just like recipes. The students in the experimental group followed up the new sheets curiously during the experiments. They were much more curious about the experiment according to the control group. Priemer (2006) indicates that successfull students in science don't prefer expository experiments. Open-ended experiements are also not very useful for science lessons because of limited duration of science lessons and crowded classes. As Abrahams and Millar (2008) staded in their recent research the teachers who use "recipe style" tasks explain this as having insufficient time for more open and unstructured manner tasks. To acquire the scientific process skills with traditional methods is very difficult. Practical work should be used by teachers to teach the scientific process skills to their students. As Temiz (2001) states, the teachers have problems with the student's of gaining the scientific process skills in the learning enviroments which they organize in traditional methods. Aim-gapped experiments are useful to improve scientific process skills of sudents. Aim-gapped experimentation technique is useful because it make students curious, is not not like just "recipe style", is suitable for crowded classes and does'nt require much time. As a suggestion aim-gapped experiments should take place as practical work in school science lessons.

THE INFLUENCE OF CONTENT AND LANGUAGE INTEGRATED LEARNING ON CONTENT PERFORMANCE IN MAGNETISM

Claudia Haagen[1] and Martin Hopf[1]

[1]University of Vienna, Austrian Education Competence Centre Physics

Abstract: Content and Language Integrated Learning (CLIL) is a bilingual teaching method, where content area subjects are taught with a foreign language as a medium of instruction while the first-language plays no or only a very subordinate role. As reaction to a moderate output of foreign language teaching, the Austrian Ministry of Education introduced this concept in the mid 1990s. Compared to conventional bilingual school programmes, CLIL is a flexible concept that can be used in all non language subjects, in all school forms on the secondary level. Positive effects of CLIL on second-language learning have been shown in numerous empirical studies. On the contrary, little is known about the influence of CLIL on students' content performance in general. For the subject physics, a first step in investigating CLIL's effect on content achievement was made by a field study. The investigation was based on a pre- and post-test design. The population consisted of 205 grade 11 students, from 6 different Austrian High Schools. Based on a control-group design, students were instructed in magnetism either in their first language (control-group) or in English (test-group). Students' subject knowledge in the field of magnetism was tested in both groups before and after the instruction with an assessment tool developed for this study. According to the analysis of data obtained, differences between both groups' subject achievement could not be observed.

Keywords: language integration, magnetism, comparative study,

1. INTRODUCTION

Content and Language Integrated Learning (CLIL) is a bilingual teaching method, where content area subjects are taught with a foreign language as a medium of instruction while the first-language plays no or only a very subordinate role.

As a reaction to advancing globalization and moderate output of language teaching, especially in the domain of communicative competence, the Austrian Ministry of Education introduced this concept in the mid 1990s. The two main objectives, followed by launching CLIL were first to improve foreign language education and second to deepen intercultural learning (BM:BWK 2008).

Compared to conventional bilingual school programmes, which have played a subordinate role in the Austrian education landscape, CLIL is a flexible concept. It can be used in all non language subjects in all school forms on secondary level and its intensity can range from teaching isolated topics in one subject to courses lasting for a school year in one or more subjects (Abuja & Heindler 1998).

So far the CLIL-concept has been introduced by many schools in German speaking countries. The number of schools applying this bilingual teaching method in one or more subjects or conducting CLIL-projects is still increasing. Science is, however, poorly represented among the subjects using a content and language learning approach. The two main reasons for this situation are that science teachers feel in many cases not confident enough in their second language, many teachers are concerned about the impact of CLIL on their students' achievement.

Evaluating the output of CLIL, two different domains are relevant: the aspect of second-language learning and that of content learning. As far as students' achievement in second-language learning is concerned, quite a number of empirical studies have proved that CLIL offers linguistic advantages. CLIL students generally outperform students conventionally instructed in English in the domain of communicative competence (Wesche 2002). They possess a significantly larger passive and active range of vocabulary and are more fluent (Dalton-Puffer 2008).

On the other hand, the subject specific effectiveness of CLIL is discussed on the basis of beliefs of current teaching practice rather than on empirically proved arguments. Here ideas, like the influence of CLIL on subject related motivation or its contribution to a deeper subject understanding due to deeper information processing are propagated (Koch & Buender 2006; Bonnet 2004).

What we know from research shows a different picture. Although, several evaluations classify CLIL as successful on the level of content-achievement, a closer examination of these results reveals weak spots like small samples and non-standardized procedures of evaluation (comparison of grades or self-evaluation). So far hardly any attempts have been made to replicate these results with standardized knowledge tests or concept inventories. In addition, the majority of investigations was carried out in subjects most frequently using a content and language integrated approach, like history or geography (Hollenweger et al. 2005). Here the question arises, whether results concerning CLIL's influence on content achievement can be transferred between two subjects emerging from different epistemological traditions (e.g. history and physics).

All in all, little is known about the influence of CLIL on content achievement in physics so far. As a starting point, a study (Author 2005) comparing the performance of students instructed either with a content and language integrated approach in English or in their first language German, was carried out for the topic of magnetism in grade 11.

The main research questions of this field study "Introduction into Magnetism" focused on effects of CLIL on content-achievement, gender performance and lesson communication.

2. METHODS

The investigation was based on a pre and post-test design, with test and control group. The population consisted of 205 Year 11 students from 6 different Austrian High Schools. The 11 classes selected did not have any experience with content and language integrated instructional approaches.78 students were instructed in their first-language (control group, CG) and 127 in English as working language (test group, TG).

For the treatment an instructional arrangement of four lessons on introductory magnetism was developed, based on methodological guidelines deriving from literature on CLIL (Thuermann 2002; Wildhage & Otten 2003; Zydatiß 2010).

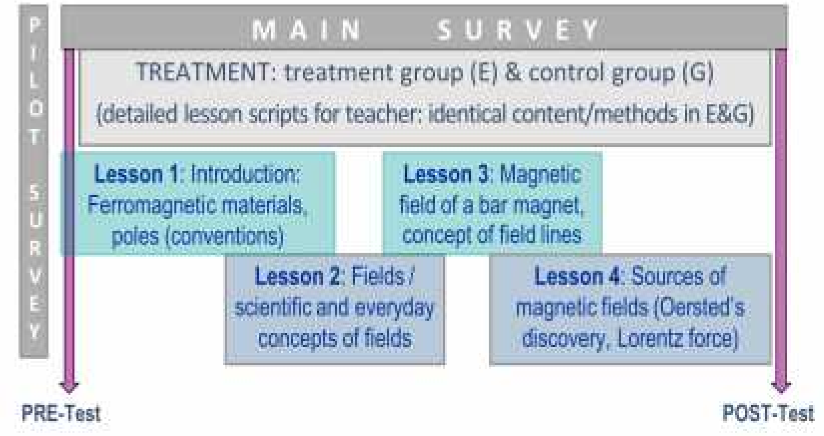

Figure 1: Research Design

Detailed lesson scripts including didactic, methodical and content related guidelines were provided for all teachers. The materials made available for teachers of both groups differed only in the language used; the content treated and teaching methods used were identical.

Since test instruments available for magnetism did not meet the needs for this study, an assessment tool, measuring students' content knowledge in the subarea of magnetism treated, was developed.

The knowledge test consisted of 21 items (6 scales) in the pre-test version (α=0.716) and of 27 items (8 scales) in the post-test version (α=0.775). Non cognitive items of the test focused on lesson communication and on personal data.

3. RESULTS

The analysis of data indicates that the language of instruction did not have much influence on the content achievement. The subject related performance of both groups was analyzed in two categories: students' self evaluation was checked and at the same time, measurements were taken by the knowledge test developed for this study. The comparison of pre-test and post-test data of students' self evaluated learning effects showed moderate to big effects for the test group (d=0.7) and for the control group (d=0.81).

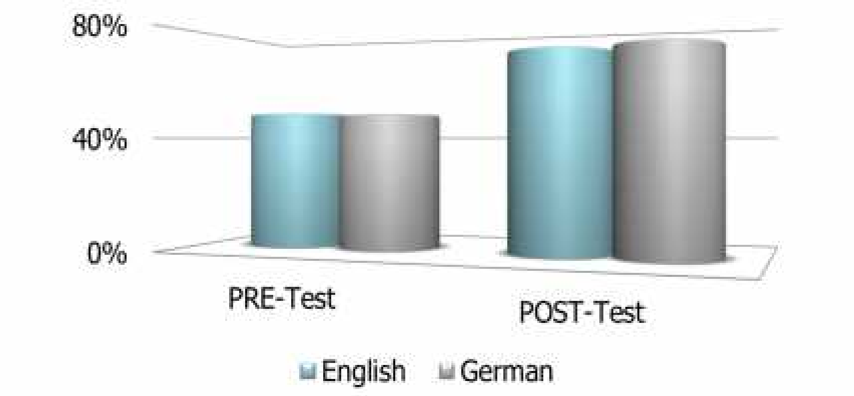

Figure 2: Subject related performance in pre- and post-knowledge test for test group (English) and control group (German)

The results of the knowledge test confirm these subjective impressions about the treatment. Learning effects achieved by the interventions in both groups are medium for both languages of instruction ($d_{testgroup}$=0.602; $d_{controlgroup}$=0.640). Statistical analysis also proves, that there is no significant difference between test and control group.

The gender analyses of the knowledge test also shows the well known effect that male students perform significantly better than female students. Achievement gains in the post-test showed, however, a small advantage for female students of both groups.

Further results were obtained concerning the effects CLIL had on the lesson communication. The majority of students experienced a balance between positive and negative effects, although these students had not had any CLIL experience before.

4. CONCLUSIONS AND IMPLICATIONS

The status of research on content and language integrated learning approaches (in physics) can be summarized as follows: while language learning advantages are already empirically proved, the influence of CLIL on content-achievement is at the very beginning. The study presented in this paper may be seen as a first step. The field study on magnetism shows that CLIL can be as successful as instruction in the first-language in terms of content-achievement. Although the test group did not have any experiences with content and language integrated learning before, they did equally well in the knowledge test. However, these results cannot be generalized for the effect of CLIL on content-achievement in physics, since they were achieved in a certain age group and with a certain topic.

As far as gender is concerned the relative gain in content knowledge is rather equally distributed among sexes. This might be a hint that CLIL can provide a learning environment quite equivalent in terms of gender.

GRAPHS IN UPPER SECONDARY SCHOOL CHEMISTRY EDUCATION

Marja Happonen[1] and Maija Aksela[1]
[1]The Unit of Chemistry Teacher Education, Department of Chemistry, University of Helsinki

Abstract : Graphs are important in elucidating chemical concepts. The present study determines the role of graphs in upper secondary school chemistry education in Finland by analyzing chemistry textbooks. The employed research method is content analysis. Three upper secondary school chemistry textbook series, 15 books in total, were randomly selected as research material. The research was guided by following questions: 1. How many graphs are there in upper secondary school chemistry textbooks?, 2. Where are the graphs located in textual context?, 3. How are they presented?, and 4. In teaching of which chemical concepts are they used? The results suggest that graphs have a very central role in upper secondary school chemistry education. The total number of graphs was high in text (N=116) as well as in tasks (N=66), and in draw a graph exercises (N=50). Most of the graphs were located within the body text. The graphs were used to illustrate several chemical concepts and phenomena. The most common use of graphs was in visualizing reaction energy and reaction kinetics.

THEORETICAL BACKGROUND

Graphs have been important tools in natural sciences ever since they were invented in the 16th Century. Graph was invented to help in perceiving the connections between different quantities. It can be described as a cultural tool – interpreting graphs requires cultural background knowledge (Vygotski, 1979). Some difficulties in learning natural scientific subjects can be related to poor graphic literacy that hinders the ability to apply mathematics to natural sciences (Tversky, 2002). Graphical abilities are a combination of three different elements: a) interpretation, the ability to transform a graph into written text, b) modeling, the ability to produce graphs from the experiments, c) transforming, the ability to produce multiple different graphs from the same experiment (Kwon, 2002).

Learning from graphs is noted to be challenging for students in many contexts of natural sciences, because it requires examining multiple concepts simultaneously (Orton & Roper, 2000). Students may have conceptual difficulties in understanding the graphs (Atar, 2002; Friedler, Nachimias & Linn, 1990). The previous studies have shown that students have difficulties in identifying the graph and choosing between the x-axis and y-axis (Aksela, 2005).

The basic knowledge of graphs is usually gained in mathematics courses. In Finland, the use of graphs in high school chemistry education is mentioned in the National Core Curriculum (The Finnish National Board of Education, 2003) as a focal objective only in examining phenomena relating to chemical equilibrium through experimentation and by using models. The transfer of learning from one subject to another requires contexts that cross the borders between the subjects (Rauste-von Wright & von Wright 1994). Textbooks have a central role in chemistry education, and they are used as reference in 95% of the teaching (Ahtineva, 2000).

RESEARCH METHOD

The research method of the present study is content analysis. The research was guided by the following questions: 1. How many graphs are there in upper secondary school chemistry textbooks?, 2. Where are the graphs located in the textual context?, 3. How are they presented?, and 4. In teaching of which chemical concepts are they used?

Three chemistry textbook series out of five available ones were randomly selected as research material. The textbooks for chemistry courses 1 to 5 were analyzed from each series. The total number of books was 15. The research was predefined to focus on actual course books that the students use. To determine the reliability of the research, three of the books were selected for reanalysis. The graphs were studied according to 27 absolute variables [(1,0) or (0, 1, 2…)] and one classifying variable (Lodico et al. 2006).

Table 1. Variables in the textbook analysis.

FUNCTION OF VARIABLE	ANALYSED FUNCTION	VARIABLES
Concepts	Classified according to the Finnish National Curriculum	Classifying (1, 2, 3… .20)
Course	Chemistry course number	Absolute (1, 2, 3, 4, 5)
Textbook series	Each series was numbered	Absolute (1, 2, 3)
Main division: location	In task	Absolute (0, 1, 2, 3…) Number N
	Between text	Absolute (0, 1, 2, 3…) Number N
	Aside text chapter	Absolute (0, 1, 2, 3…) Number N
	Extra chapter or text box	Absolute (0, 1, 2, 3…) Number N
	Draw a graph: experimental	Absolute (0, 1, 2, 3…) Number N
	Draw a graph: literature	Absolute (0, 1, 2, 3…) Number N
Tasks:	Draw / fill	Absolute (0, 1)
	Read results	Absolute (0, 1)
	Explain	Absolute (0, 1)
	Analyze / Evaluate	Absolute (0, 1)
	Calculate	Absolute (0, 1)
Explaining the graph	Connection between the axes is explained in the text	Absolute (0, 1)
	Caption	Absolute (0, 1)
	Explanation in the caption	Absolute (0, 1)
	Named properly	Absolute (0, 1)
	Word function connected	Absolute (0, 1)
Pictures	Pictures in the graph	Absolute (0, 1, 2, …) Number N
Axes	Name and / or unit in the x-axis	Absolute (0, 1, 2)

	Numbers in x-axis	Absolute (0, 1)
	Name and / or unit in the y-axis	Absolute (0, 1, 2)
	Numbers in y-axis	Absolute (0,1)
Graphs	Visible points	Absolute (0,1)
	How many curves / graphs in one graphical representation	Absolute (0, 1, 2, 3,….) Number N
	Derivate or slope	Absolute (0,1)
	Integration application or surface area (distribution functions)	Absolute (0,1)

The analysis was done with SPSS-program.

RESULTS

In total, there were 232 graphs or graph tasks in the research material that were included in the analysis. The total number of graphs was 182, out of which 90 were located within the body text, 13 in the side column, 13 in the extra chapters, and 66 in the tasks. In addition, the textbooks included altogether 50 exercises to draw graphs, which were analyzed under the task category. (See Charts 1 and 2.)

Many significant conclusions can be drawn from the data. 43% of the graphs were properly identified. The points were marked to 16% of the graphs. Derivative or integral was not mentioned with any of the graphs. The concept of function was mentioned with 13% of the graphs, but it was used in expressions such as “the function of something”, not as a mathematical entity.

The graphs were used in teaching of nine particular chemical concepts. The most common use of graphs was in visualizing reaction energy (see Chart 2).

Chart 1. The number and location of graphs by the upper secondary school course.

Location of Graphs / Course	Between text chapters	Beside text	In extra-chapter	In task	Draw a graph: practical work	Draw a graph: in text / table	Total (N)	Total (%)
Course 1	7	0	1	2	0	3	13	6
Course 2	19	2	2	14	3	1	41	18
Course 3	35	4	9	18	12	12	90	39
Course 4	0	0	0	3	3	2	8	3
Course 5	29	7	1	29	2	12	80	34
Total (N)	90	13	13	66	20	30	232	100
Total (%)	39	6	6	28	9	13	100	

Chart 2. The frequencies in the use of graphs in teaching of different concepts. *c, m, n, V or x plotted versus time.

Location of graphs Context / Context	Between text chapters	Beside text	In extra-chapter	In task	Draw a graph: practical work	Draw a graph: in text / table	Total (N)	Total (%)
Solubility	4	1	0	7	2	1	15	6
Titration	8	0	1	12	8	2	31	13

Total (N)	90	13	13	66	20	30	232	100
Total (%)	39	6	6	28	9	13	100	

CONCLUSIONS

The present study shows that graphs have a focal role in upper secondary school chemistry education in Finland. The number of graphs within the text and in tasks is high. The importance is highlighted by the fact that the graphs are usually located within the body text. In the textbooks for courses 3 and 4, the amount of graphs is so high that insufficient graphic literacy could be reflected in learning. There should be more focus on teaching about graphs during chemistry lessons.

In the data, there was a constant lack of sufficient identifying of the graphs; less than half of them were identified properly. More attention should be paid in the identification as, according to previous studies, students have difficulties in identifying graphs (Aksela, 2005). The research also shows an evident lack of mathematical functions in the background of chemical graphs. The graphs function as visual displays of research results, but their mathematical evaluation is scarce in upper secondary school chemistry, or the results are evaluated from the perspective of one point, not the whole function.

Lines are fitted within the graphs, but instead of placing value on the function, only one point is analyzed. It could be stated that the way upper secondary school students use graphs is similar to drawing connections in the graph without mathematical functions or equations in Galileo Galilei’s time. According to previous studies, the lack of function can make perceiving the graph and interpreting it intuitively more challenging for students (Leinhardt, 1990).

The use of graphs in supporting chemistry teaching requires the students to understand the characteristics of graphs and apply the information the graphs represent to support the learning process. There is a demand for diverse approaches to support learning.

THE EFFECT OF BRAIN BASED LEARNING ON ACADEMIC SUCCESS, ATTITUDE AND RETRIEVAL OF INFORMATION IN SCIENCE AND TECHNOLOGY CLASSES

Nuray İNCİ[1] and Hilmi ERTEN[2]

[1,2] University of Fırat

Abstract: The purpose of the study was to examine the effect of Brain-Based Learning approach on achievement, attitude and retention of knowledge in 8th grade students' science and technology classes.

Brain based learning, which focuses on the ways the brain learns best rather than the ways of teaching, with a rich learning environment and trigger of thinkings.

The pre/post-test control group research model was used in this study. The research was conducted with one experimental group and one control group in 2008-2009 academic years. Totally 30 students, participated in this research. The study took place during the teaching of "State of Matter and Heat'' with of the science and technology course. In the experimental group, students were taught according to the brain-based learning approach, while in control group students were taught according to the traditional methods.

The data obtained were analyzed using the SPSS program for Mann Whitney U Test, Friedman Test and Wilcoxon Sign Rank Test. The means and standard deviations were calculated for groups.

The results demonstrated that there was a statistically significant difference on achievement, attitude and retention, conclude of brain-based learning, between the experimental group and the control group, in favor of the experimental group.

Keywords: Brain Based Learning, Science and Technology Teaching, Achievement, Attitude, Retention.

INTRODUCTION:

Brain is a structure inside the skull consisting of more than 100 billion neurons. A neuron transmits a received stimulus to another neuron at a speed higher than 380 km/h. The striking speed of the transmission of stimulus is a feature arising from the closeness of neurons. When volume and mass of the brain is taken into consideration, there are approximately 10 million neurons in each centimeter cube of the brain. İnci (2010) defines brain as an exceptional organ in which countless mysteries are woven and different features of which are explored and written by the ink of time every moment.

While the brain hosts every kind of learning in a unique way, the factor of environment should never be ignored and the question of how the best way of learning can be achieved within a rich life pattern by using various motivation factors and individual's spheres of interest, too.

Brain Based Learning (BBL) is a holistic approach regarding learning with a developmental and socio-cultural perspective based on the structure and functions of the human brain (Caine & Caine,1995). This learning theory is based on the structure and function of the brain research came from advances in neuroscience. Brain Based Learning is a Learning approach that is based on the structure and function of the human brain. Different than traditional methods, brain based learning emphasizes meaningful learning instead of

memorization. Brain-Based Learning takes into consideration a student's brain as a whole when it comes to learning. Often, we look at a student's learning style as the street to educate them. However, there are multiple ways of learning, and each of us might utilize different aspects and areas of our brains in order to process information in the most efficient manner.
Brain-based teaching incorporates three instructional techniques:
*Orchestrated immersion – Creating an educational experience that immerses students in higher-order thinking, making connections relevant, and using creativity to design learning environments. * Relaxed alertness – An atmosphere that is low threat and high challenge. The goal is to eliminate stress and fear that inhibit learning and provide a learning environment that is positive, non-threatening and challenging. *Active processing – Students need time to consolidate and internalize information by actively processing it (Caine, 1997). According to research on brain-based learning, environments, diet, amount of sleep, and water intake all affect the way our brain responds and learns.

Brain-Mind Learning Principles: *All learning is physiological., * The Brain-Mind is social.* The search for meaning is innate. * The search for meaning occurs through patterning. *Emotions are critical to atterning. *6. The Brain-Mind processes parts and wholes simultaneously.*Learning involves both focused attention and peripheral perception.*Learning always involves conscious and unconscious processes. *There are at least two approaches to memory: archiving individual facts or skills or making sense of experience.*Learning is developmental. *Complex learning is enhanced by challenge and inhibited by threat associated with helplessness. *Each brain is uniquely organized (Caine & Caine, 1990).

Brain-Based Learning approach is student-centered. Brain-Based Learning approach could be added to the course which activates the brain of all kinds of element. For example, in science and technology issues could also be utilized from history, geography and philosophy. Students' interest in the subject area is known to be connected directly to that field. According to the students' interest in the subject area may be contacted directly.

Problem Sentence:

Is there a statistically meaningful difference between the Science and Technology class of 8th grade students in primary school regarding “States of Matters and Heat” unit who receive BBL approached and traditional education with regards to level of permanence of success of information and changes in brain dominance? In addition to, sub problems are the following; is there a statistically meaningful difference between points of pre-test, final test and permanence tests of the students in experiment group, was there a change observed in the attitudes of students in experiment and control group towards science before and after the application of BBL method, research is an experimental type of study. Pre-test – final test control group pattern was implemented.

Method:

The pre/post-test control group research model was used in this study. This study was carried out in Elazığ in the second half of 2008-2009 educational years. Work group of the study consists of 8th grade students of Alacakaya Primary School. 30 equivalent students who were chosen among 70 students by equalization participated in the study. Analysis of data was made by a packet program called SPSS 16 for Windows. Friedman, MWU tests with frequency and percentage values were used in the analysis of data.

Data Collection Tools:

Data collection tools are brain dominance tool, achievement test and attitude test. Brain hemispheres have effective roles in different functions.‘Brain dominance’concept is used to express the dominance of one hemisphere of brain to the other in some specific function. Brain dominance tool, Davis and others (1994) adopted by the tool. The original of tool; 39 items and each item the right hemisphere of the brain, the left hemisphere and both used the equal dominance, contains three options. We used the form translated to Turkish of Davis's Brain dominance tool. This tool consists of 26 items. The validity and reliability study of the Turkish version of Brain dominance tool was conducted by Avcı (2006), 200 primary 7th grade student on the applied and the reliability coefficient is calculated as 0,70. In the evaluation of the brain dominance tool utilized from the ranges of values and definitions Mariani (1996)'s used, an evaluation criteria schedule is constructed.

Steps in the evaluation of brain dominance tool are as follows;

In evaluation of items, (-) sign is put in front of 'A' option, (+) sign is put in front of 'B' option. Any signs are put in front of 'C' option. According to the scores between -26 and 26, judgements are made about students' which brain hemisphere more work. Students' brain dominances are found out according to the following number ranges and definitions:
*Range from -26 to -21: Left Brain Dominance (very strong), *Range from -20 to -15: Left-brain Dominance, *Range from -8 to -14: Left Brain Dominance (More Dominant), *Range from -7 and -1 range: Left Brain Dominance (Less dominant), *0: The two sides of the brain the same dominant (The same dominance), *Range from +1 through +7 range: Right Brain Dominance (Less dominant), *Range from +8 to +14 range: Right- Brain Dominance (More Dominant), *Range from +15 to +20 range:Right-Brain Dominance, *Range from +26 to +21 range: Right- Brain Dominance (very strong).

A pilot application was made in order to assess the impact of data collection tools on students and the level of clearness and understandability of the study and if it serves its purpose. Another purpose of this pilot application is to increase the validity and credibility of the study. In this context, unit of "States of Matter and Heat" was covered with materials prepared in compliance with BBL. Posters, formulas and rules written on colorful balloons, various laboratory tools and devices to be used during the class and audio visual recording devices were prepared before class according to the quality of the subject to be learnt. With some students, the clips filmed outside the classroom.

For the achievement test 22 multiple choice questions were prepared about the unit of "States of Matter and Heat". Questions were prepared by the researcher based on the textbooks and activity books of Ministry of Education (MEB in Turkey) used in 8th grade. Alpha credibility coefficient of the test was calculated as 0.84, average difficulty was calculated as 0.73 and average distinguishing capacity was calculated as 0.45 as a result of analyses. Achievement test as implemented as pre-test, final test and permanence test to experiment and control group students.

As most of the experiment group students use their left brain, objects to activate the right brain were chosen during preparation process of the class, however left brain was not neglected. For instance, students were sometimes asked to close their eyes and imagine or to draw a picture or a caricature about the subject during the class. As a result of in class observations, it was seen that even some students who try to disguise behind the lie of "I don't understand" start to develop a salient interest and desire to learn.

Short videos (clips) were shot in which students took part specifying the important parts in text and activity books regarding the unit of "States of Matter and Heat" while covering the subject with BBL method. Experiment group students watched this video at regular intervals and it was found out that their interest in the lesson increased in a positive way. These clips helped students in understanding the topic. By using of popular music in clips, were lyrics changed (were adapted to science and technology). So, the course content objects were presented in an entertaining way with video-clips in certain periods. Thus, it was provided that the subject took place in their minds in a more efficient way.

Findings derived from the study are restricted with the data derived from the students attending classes 8-A and 8-B in Alacakaya Primary School in Elazığ during 2008-2009 educational years, Science and Technology lesson's unit of "States of Matter and Heat" as well as tests prepared by the researcher and brain's dominance tool. In order to determine the equivalence of the groups, the averages scores of the students in both groups have been compared with the personal information questionnaire and science and technology school report scores of the groups have been taken into consideration.

FINDINGS:

Brain dominance instrument to the experiment group students was applied before and after the experimental process. The purpose of a supply of experimental post-process, students' brain dominance BBL method to discover whether there really is causing a change. The levels of brain dominance of the students in experiment group is usually left brain dominant (before the experimental process). There are left brain dominance (less dominant) students are %73, the two sides of the brain the same dominant students are %7, right brain dominance (less dominant) students are %20, according the evaluation (Brain dominance tool scores of the students in experiment group). Seven students' have been changes in the brain dominance after the application BBL (Table 1).

Table 1: Those who change in the brain dominance after the application BBL

Before the application BBL	**Evaluation**	**After the application BBL**	**Evaluation**	**Those who change in the brain dominance**
-3	Left brain less dominant	-2	Left brain less dominant	
1	Right brain less dominant	-4	Left brain less dominant	*
-2	Left brain less dominant	2	Right brain less dominant	*
-7	Left brain less dominant	-1	Left brain less dominant	
2	Right brain less dominant	-1	Left brain less dominant	*
7	Right brain less dominant	-3	Left brain less dominant	*
-2	Left brain less dominant	-1	Left brain less dominant	
-3	Left brain less dominant	1	Right brain less dominant	*
-1	Left brain less dominant	4	Right brain less dominant	*
-5	Left brain less dominant	-6	Left brain less dominant	
-4	Left brain less dominant	-2	Left brain less dominant	
-4	Left brain less dominant	-4	Left brain less dominant	
-1	Left brain less dominant	-1	Left brain less dominant	
-2	Left brain less dominant	1	Right brain less dominant	*
0	The two sides of the brain the same dominant	0	The two sides of the brain the same dominant	

The Friedman Test is used to test hypotheses involving several measurements obtained from the same group. Friedman test was applied to experiment group students in order to specify if there is a statistically meaningful difference between their results of pre-test, post-test and permanence tests.

Table 2: The Mean Ranks of the Experimental Group for Pre-test, Post-test and Follow-up Scores of academic achievement tests.

Tests	**n**	**Mean**	**Sd**	**Mean rank**	**X²**	**df**	**p**
Pre test	15	14,8000	2,67795	1,17	18,750	2	,000*
Post test	15	18,8667	1,50555	2,67			
Permanence test	15	17,7333	2,28244	2,17			

According to the results of Friedman test which was applied to reveal if there is an important role of permanence test which was applied for about three months later, final test that was applied just after the lesson and pre-test which was applied before BBL method, a statistically meaningful difference of the points of the achievement tests applied at regular intervals on the permanence of information (X^2 (df=2, n=15)=18.750, p< .05). As a result, it can be concluded that BBL method is efficient in making the information permanent.

Table 3: The Wilcoxon Signed Rank Test as a post-hoc test results

		Wilcoxon Matched Pairs Signed Test			
Post test-Pre test	**n**	**Mean rank**	**Sum of Rank**	**z**	**p**
– Ranks	0	,00	,00	-3,306	,001*
+ Ranks	14	7,50	105,00		
Ties	1				
Total	15				
Post test-follow up test – Ranks	3	5,83	17,50	-1,697	,090
+Ranks	9	6,72	60,50		
Ties	3				
Total	15				
Follow up-Pre test – Ranks	2	4,00	8,00	-2,990	,003*
+Ranks	13	8,62	112,00		
Ties	0				
Total	15				

According to the results of Wilcoxon Signed Rank test which was applied post hoc, the statistically meaningful difference between pre-test and final-test results of experiment group students is (z=-3,306, p< ,05) whereas the difference is (z=-2,990, p< ,05) between the pre-test and the permanence test. However, no statistically meaningful difference was found between the measurements according to the results of Wilcoxon Signed Rank test which was applied post hoc even if Friedman test says that there is a meaningful difference between the points attained from post test-permanence test.

Table 4. The Mean Ranks of the Control Group for Pre-test, Post-test and Follow-up Scores of academic achievement tests.

Tests	**n**	**Mean**	**Sd**	**Mean Rank**	**X²**	**df**	**p**
Pre- test	15	12,8000	2,83347	1,97	,250	2	,882
Post- test	15	12,8667	2,13363	2,10			
Permanence Test	15	12,6000	1,99284	1,93			

According to the results of Friedman test, no statistically meaningful difference was found of the points of achievement tests which were applied to control group students at regular intervals on the permanence of learnt information (x^2 (df=2, n=15)= ,250, p> ,05). As a result, it can be said that traditional methods are not sufficient to ensure the permanence of learnt information.

Table 5. The Mean Ranks of the Experimental and Control Group students for science and technology pre- attitude test score

Mann-Whitney U Test						
Groups	**n**	**Mean Rank**	**Sum of Rank**	**MWU**	**z**	**p**
Experiment Group	15	13,90	208,50	88,500	-1,001	,317
Control Group	15	17,10	256,50			

According to attitude pre-tests which were applied to experiment and control group students before the application of BBL method, there is no salient difference between the attitudes of students towards Science and Technology (U=88,500, p>0,05). Namely, groups were equivalent in their attitudes towards science before the application of BBL method.

Table 6. The Mean Ranks of the Experimental and Control Group students for science and technology post- attitude test score

Mann-Whitney U Test						
Groups	**n**	**Mean Rank**	**Sum of Rank**	**MWU**	**z**	**p**
Experiment Group	15	21,10	316,50	28,500	-3,501	,000*
Control Group	15	9,90	148,50			

Mann Whitney U Test was applied in order to test the hypothesis claiming that there is a statistically meaningful difference between the attitudes and perception levels of students receiving traditional education and students receiving education in accordance with BBL method regarding science after the experimental processes. Accordingly, there is a salient difference between the points of attitudes of students of experiment and control groups toward Science and Technology (U= 28,500; p<0,05). The fact that BBL has changed students' points of view can be mentioned among the reasons of the difference to the advantage of experiment group.

CONCLUSION

Brain is so strong that, it is impossible to talk about something difficult for a properly motivated and programmed brain. As for our imagination, it has no limits. As a matter of fact, inventions of today have come true as a product of some people's imaginations.

Our students are both going to learn without getting bored and take firmer and more confident steps along the path of success in an environment enriched by components to make brain more active.

In our study, it was clearly observed that even the students saying that they don't like science classes took an interest in science. When both teacher and students come to class getting prepared before with various materials and students learn information one to one and interpret by projects and performance homework; therefore different zones of the brain are activated and hormones of happiness are released in brain along with the success accompanied by productivity.

Upbeat or relaxing music was played during the classes. For example songs were composed such as "Gar mı yağmış şu Harput'un başına, Gurban olam toprağına daşına" (Did snow fall down on Harput, May I give my life for its land) (resembling a Turkish folk song) and these songs were adapted to the subject. In addition, ‘’There is a huge difference between heat and temperature...’’ and so on. sentences clips were filmed.

This information can be used in the classroom to create vibrant learning environments. Other suggestions on how to integrate brain-based teaching include: incorporate learning with storytelling. Storytelling is an effective way to ground the meaning in structure and provide for emotion. Provide structure – connect today’s material with previous and future material to help each person as he/she seeks to make sense of the information he/she hears or sees. Speculations, experiments, question and answer sessions, hold debates, games, music, songs are used role playing to embed information into the student’s long-term memory.

Relaxing movements were made when they got bored and they were allowed to bring their needs to the classroom such as water. Among the reasons why students like BBL method, building a comfortable learning environment can be counted. So every object to activate the brain is seen as a tool for the class.

There is a meaningful difference between recalling levels of students of the control group to which traditional teaching methods were applied and experiment group to which BBL approach was applied to the advantage of experiment group in Science and Technology class. Namely, BBL approach is more effective than traditional education in increasing recalling level.

There is a meaningful difference between attitudes of students of the control group towards science to which traditional teaching methods were applied and experiment group to which BBL approach was applied to the advantage of experiment group in Science and Technology class. It can be said that BBL approach is more efficient than traditional education in developing positive attitudes towards science. Obtained results are also parallel with the literature.

At the end of the research, it is revealed that the students who are educated by the Brain-Based Learning method are more successful and have a higher motivation than the students who are educated by the traditional instruction methods. Each brain thinks different. Each brain looks different windows to the world. With different brains in the future to be applied with brain-based learning method not only in the teaching of science, other areas will increase the success and future of education is a fact that more enjoyable

Abstract: The actual designing process of three school teachers about "mixtures and solutions" course is analyzed and categorized within a threefold dimension system: scientific/school knowledge epistemology, PCK and teacher professional identity. The "process matrix" thus constructed helps the understanding of the individual methodological process.

Keywords: grade 3–5, teaching process, course design, process matrix, mixtures and solutions.

INTRODUCTION

This presentation relates to ongoing research in the preparation of a thesis in science education. We are interested in the work of teachers in last elementary grades in France and especially in the designing process of teaching sequences about "mixtures and solutions."

This study is obviously motivated by heuristic considerations but also by the concern to produce a theoretical framework that can contribute to the instrumentation of the training of primary schools' teachers. To achieve this goal, we have built a framework to help reflexivity during the designing of lessons. This is to give teachers the possibility to identify and choose the nature and identity of their own teaching approach.

DESCRIPTION, REPRESENTATION AND INTERVENTION PURPOSES

This study aims to describe the nature and identity of the taught knowledges (Lebeaume, 2000) and the nature and identity of the teaching processes as reported by last grades elementary school teachers during the phases of the designing of the courses. It also aims to represent the guidance of the course (Astolfi, 1991), as it appears during the designing process. To do so we intend to characterize the intentions expressed by the teacher as well as the resources (both material and intellectual) he uses. The teachers' conceptions are part of some "self-didactics", individual and contextual. The identification of those conceptions contributes to enlighten the gap that may exist between the principles summoned (teaching and learning) and what the practical implementation process reflects. This is, ultimately, to contribute to the designing of a suitable *didactical space* (Calmettes, 2009) to describe the processes of teaching.

Finally, this study aims to build tools for intervention in initial and continuing training of primary school teachers. These should promote awareness of the nature and identity of individual teaching processes; it should also give the opportunity to discuss the suitability of a given teaching process with a clearly identified didactical intention.

THEORETICAL BACKGROUND

Curricular approaches

We use various general categories related to curriculum studies (Audigier and Crahay, 2006; Forquin, 2005): those related to the development of a formal curriculum (recommended curriculum, written/mandatory curriculum, supported curriculum) as well as those related to the actual activity of teaching (taught curriculum, assessed curriculum, hidden curriculum) leading to real learning (learned curriculum, latent curriculum).

The question of the nature and identity of content and processes

We intend to study the nature and identity of the knowledges that the teacher claims to teach as well as the corresponding teaching process that he reports.

Curricular didactical approach

With the concept of *curricular matrix* Lebeaume (2000) proposes to describe the nature and identity of technological education in France. This approach seems transposable to help inform the question of the nature and identity of knowledge (and actions) that the teacher claims to teach.

Dimensions of science education: knowledges, familiarity with scientific practices and epistemology

The school knowledges to be taught and the taught school knowledges are considered in their own and actual individuality. The question of genetic or teleological relationships they have with the academic knowledges (Chevallard, 1991) or *reference social practices* (Martinand, 1986) underpins the discussion about their identity and their nature.

Furthermore, science is a core contemporary human activity. As such, Science belongs itself to the curricula because it is a *reference social practice* that pupils have to know about.

Finally, we also have to integrate the epistemological dimension (philosophy, sociology and history) of the teaching and the part it plays within the teaching.

Science teaching processes

On one side we have the curricular prescription and on the other side we have the teachers' choices about appropriate teaching process for each of these dimensions; it is also linked to the question of the overlapping and interlacing of the teaching of these three dimensions.

Referring to Inquiry Based Science Education, studies about actual practices show pluralism and a dispersion (Calmettes, 2009), if not an inconsistency, hidden by an institutional consensus. Two extreme frameworks reflect as well the theoretical uncertainty. On one side, the inquiry pedagogical model - making reference to Dewey (Coquidé et al., 2009) – can be applied to science education. On the other side, school science inquiry can be presented as the natural transposition of scientific inquiry. In this case, we are given the justification *per se* of the relevance of such a transposition of the scientists' practices (Mathé et al., 2008). Again, we have to deal with the nature and identity of the processes used to teach knowledges to be taught within school science courses and their links with science as a social reference practice (Bisault, 2010).

We must remove semantic and didactical ambiguities. The didactical relevance of identified teaching processes needs to be assessed in the didactical field (didactical, didactics used in the French way, that is to say what refers to research about science education, in their specificity linked to the nature and identity of the knowledges to be taught as well as linked to the pupils' learning processes of these particular knowledges).

Didactical skills and epistemological skills of teachers

Teachers' didactical skills are revealed in the teaching of specific content. Related to Pedagogical Content Knowledge model (PCK) proposed by Shulmann (1986), they contribute to the guidance of the course in the designing phases. They refer to different theoretical didactical frameworks: level of formulation, problematization, conceptions …

Many studies also point to the reciprocal interactions between the epistemological conceptions of teachers and their conceptions about science education (Brickhouse, 1990; Waters-Adams, 2006). The prevalence of empirical-realistic (positivists) conceptions is particularly related to the own educational experience of teachers (Desautels et al., 1993).

Mixtures and solutions: special nature of knowledge to be taught

In the last elementary grades, the knowledges to be taught are not coming from a transposition of academic knowledges. They may even appear to be inconsistent with the concepts related to thermodynamics. The definitions (homogeneity, purity) stay at a phenomenological stage. The principle of conservation of mass during mixing is not specific to this theme. The quest for a distinction between "mixed and chemical combination" (Duhem, 1902) is of course not resolved here.

Here the knowledges to be taught refer mainly to everyday experience and social practices: the kitchen, the production of salt … they refer too to education for sustainable development: access to water, use of domestic water, wastewater treatment (mechanical stages of the treatment), water purification … the "technical abilities" that are practised here, seem to refer to everyday life as well as to the development of experimental skills (conservation mass, solubility limit).

Therefore it seems particularly interesting to see what "scientific dimension" the teachers attribute to the knowledge to be taught.

THE STUDY

Method

We have conducted case studies using the recording of the designing sessions.

We intend to be as close as possible to the practice of teachers. To do so, there are several conditions. The pace of work of the teacher is met (number of sessions, distribution of the sessions over time). For the in-service interviewed teachers, these work sessions are intended to be implemented with pupils in their actual class context.

In a process of explicitness (Vermersch, 2006), the researcher's role is to make clear the *how* of the process more than the *why*.

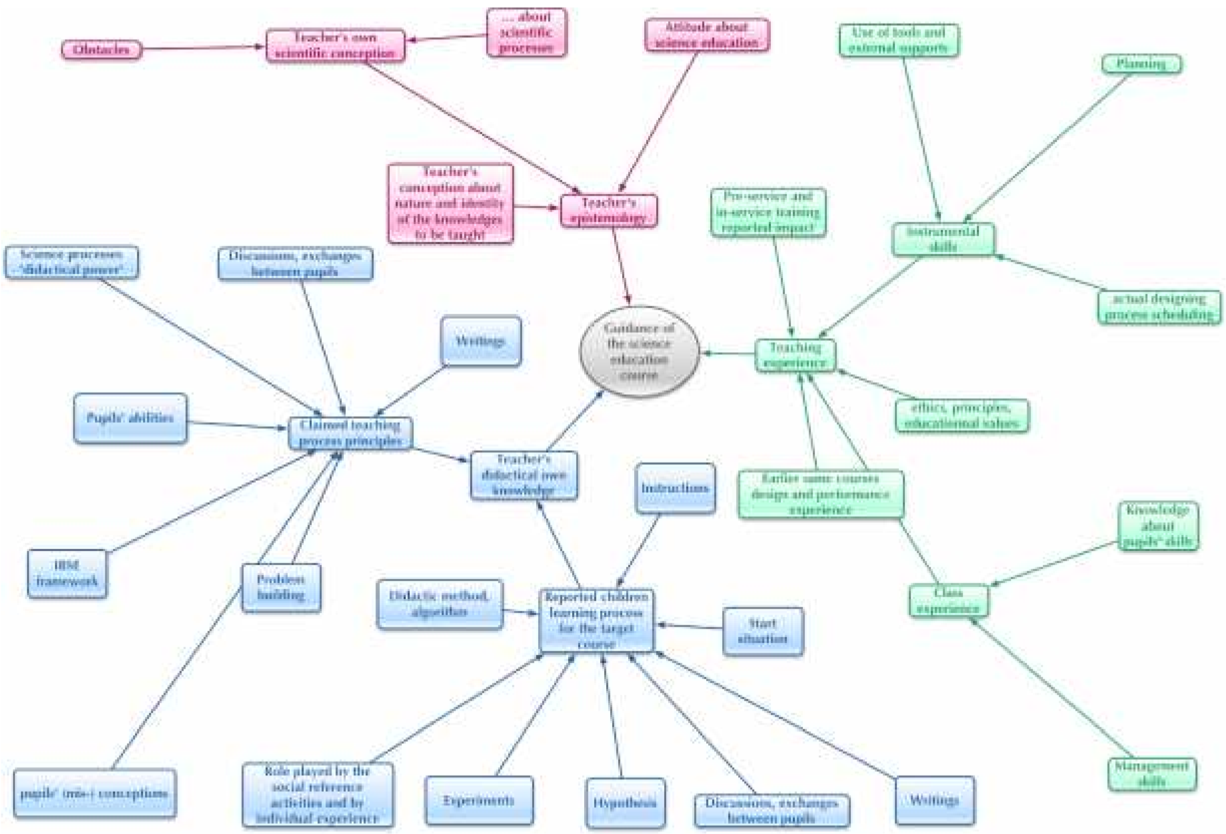
The sessions have been recorded on digital media and have been fully transcribed. The documents produced by the teacher during the sessions have been digitalized. For the analysis of the transcription, we have used a concept mapping software (Freemind). The significant elements (sentences, paragraphs) are characterized by nodes and are gradually reorganized over the analysis to achieve a mind map that fits our theoretical framework.

Target teachers

So far, we have analyzed three records:

Teacher	Seniority	Last elementary grades seniority	Remarks
alpha	22 years	All career long	Teacher-trainer
beta	20 years	9 years	Chose to work on states' changes, focusing on the mixing of states at the change of state.
gamma	Retired	All career long	Doesn't have to implement this work…

Figure 1: process matrix



Results

Global approach

We can not highlight a real difference between the way the teacher thinks the students are supposed to learn the knowledge taught and the teacher's conceptions about scientists' processes. There is no distinction made between the knowledges to be taught and the academic knowledges. The reference social practices and individual experiences are seen only as examples of applications of the concepts involved, not as an aim of teaching.

Process matrix

The designing of a course requires that the teacher solves a complex problem. The resolution of this problem demonstrates the manifestation of a contextual skill. It reflects the articulation of internal and external resources (Jonnaert, 2009).

As seen in some of our previous works (Kapala, 2010), we suggest to build what we call a *process matrix*. It refers to the categorization that comes from the analysis of designing sessions. It describes the designing of the targeted course as a combination of three dimensions (see Figure 1: process matrix).

Scientific epistemology and school knowledge epistemology of the teacher

- the conceptions of the teacher about the nature and identity of knowledge to be taught, particularly in relation to reference scientific knowledges;
- the conceptions of the teacher about science and science processes;
- the conceptions of the teacher about the "didactical power" of the "scientific processes" (connections between the conceptions of the teacher about scientific processes and the teaching processes he claims to promote);
- feelings about science education.

Teacher's PCK

- the principles stated by the teacher for teaching processes (based in particular on the knowledge of the teacher of the learning processes and the use he makes of it to design his own teaching);
- The description of the learning process as planned by the teacher for the targeted sequence.

Professional identity and experience of the teacher

- values and ethics;
- experience of the classroom (classroom management, knowledge of individual student skills, experience of similar sequences previously conducted);
- instrumental skills (programming and progressions, access to tools and external resources, actual organization of the designing work);
- part played (as reported) by the initial and continuing training.

Individual process matrix

The characterization of the discourse of the teacher during the designing phase according to this process matrix leads to define a profile. We proceed by identifying the categories that are present among those inventoried.

DISCUSSION

Some uncertainties…

This work seems to highlight some uncertainties in the discourse of the teacher characterizing the designing of the course.

Epistemological uncertainties

- academic knowledge vs. knowledge to be taught?
- Processes of scientific discovery vs. teaching/learning processes about knowledge to be taught?

Didactical uncertainties

- gap between the reported didactical intentions and the conceptions deduced from the proposed implementation;
- gap between didactical principles asserted and education actually planned;

Pedagogical uncertainties

- Opposition between autonomy and effectiveness;
- Opposition between the claiming of the value of some pedagogical principles and the expression of the identity of the teacher (super-regulator teacher, holder of authority in a transmissive way, time-keeper and syllabus-keeper).

The construction of categories and their measurement

At this point, we think about two main directions for further works. We must reasonably increase the corpus in order to stabilize the categorization proposed in the process matrix. The assessment of this categorization, eventually linked with a strong theoretical framework, will rely also on discourse analysis methods. Then we'll have to deal with the profiling of individual teachers by proposing a "measure" of categories and subcategories of the process matrix that would go beyond the binary occurrence test. For items found to be present in the individual and contextual process matrix, we would have to be able to evaluate the "weight" of each of them. This may go through a confrontation of the teacher with his or her own qualitative process matrix established by the researcher to conduct a self-assessment of the relevance and of the accuracy of the tool.

We do not address here the crucial issue of effective implementation of the course with the pupils. However fundamental and important, the comparison between the didactical analysis of the in-class interaction with the analysis we propose at the designing stage is a longer term objective.

[2]University of Bremen, Germany

Abstract: This paper gives an overview about the project 'SALiS– Student Active Learning in Science', funded by the TEMPUS program of the EU for 2010-2012. SAliS is a reform initiative for middle and eastern European countries to innovate science teaching and teacher education. SALiS seeks to overcome a centralized and teacher-centered paradigm in science education as it is still predominant in different countries of central and Eastern Europe. Intended change concerns more student-active and problem-based science education under inclusion of students' hands-on and inquiry-based learning in the lab. Within an international network, ten partners from six countries work on establishing sustainable change i.e. in the training practices of prospective and in-service science teachers.

Keywords: science teacher training, curriculum innovation, inquiry-based science education, active learning, EU-projects

BACKGROUND

Science teaching pedagogies in many countries all over the world are still dominated by a teacher-centered approach. Although constructivism is widely accepted in science education research and theory, the practice in science classrooms in a lot of cases is still dominated by transmission oriented pedagogies of learning and instruction. This consideration is especially true for many countries in central and eastern Europe which are still on their way of reform from the communist time towards modern educational systems and practices (Kapanadze, Janashia & Eilks, 2010).

Anyhow, reform already started. But, reform in many countries in central and eastern Europe lacks by deficits in infrastructure and resources for scientific and educational exchange. That is why in cooperation of the Ilia State University in Tbilisi, Georgia, and the University of Bremen, Germany, the project initiative '*SALiS - Student Active Learning in Science*' was launched in 2009. Together with further partners from Ireland, Bulgaria, Germany, Georgia, Moldova, and Israel, an application for a reform network was submitted to the TEMPUS program of the European Union. The project was successfully approved in summer 2010 and will be conducted 2010-2012 with ten partners from six countries.

SALiS aims at innovating science teaching through a better inclusion of inquiry-based and student-active experimental learning in science classes. The project intends to promote i.e. open and inquiry-type lab-work as one of the foundations of modern curricular and methodological approaches in science teaching (Hofstein, 2004; Hofstein & Lunetta, 2003; Kipnis & Hofstein, 2007). These approaches aim to raise motivation, allow students gaining higher order cognitive skills, promote more effective learning of science concepts, and to contribute an advanced understanding of the nature of science (Kapanadze et al., 2010).

Recognizing that the teachers are the core for any innovation in educational settings (Eilks et al., 2006), the project aims at innovating science teaching in the above mentioned sense by improving teacher training. For the purpose described, all participating institutions are jointly developing modules and resources for science teacher training in inquiry-based science education. These modules aim on enabling pre- and in-service science teachers to strengthen hands- and minds-on student learning through innovative approaches to lab-work instruction, e.g. inquiry-type strategies, open lab tasks, or cooperative learning in the lab environment (e.g. Hofstein & Mamlok-Naaman, 2008; Kipnis & Hofstein, 2007; Witteck, Most, Kienast & Eilks, 2007).

RATIONALE

SALiS is jointly developing teacher training modules, school teaching materials, and a concept of implementation of SALiS via the use of low-cost lab equipment. A series of workshops is developed to train teachers and teacher trainers in central and Eastern Europe to apply and support constructivist teaching and learning scenarios, both in teacher training and school science education. Implementation of the training modules is supported by creating a collection of good practices from all partner countries and making them available to the other partners by translation and adoption. A web-based resource pool is made available in the different languages of the countries participating in the project offering teachers and teacher trainers material to innovate experiment-oriented and inquiry-based science education, e.g. in the field of low-cost-experimental techniques. A platform for exchange of inquiry-based and student-centered science lab activities for students in secondary schools and secondary science teacher training courses will be established.

Whereas respective facilities at least on a basic level are available in all SALiS partners from the EU countries, the project will strengthen the infrastructure in the six beneficiary institutions through equipping science laboratories for teacher training. SALiS is providing a concept of necessary infrastructure for respective teacher training labs. With funding from the EU necessary equipment for training teachers in SALiS-oriented and lab-based pedagogies feasible to the curricular targets of SALiS are installed. Detailed guides that describe the usage of laboratories in teacher training including questions of safety, logistics and maintenance issues are developed, and structures of curriculum materials describing lab activities for teacher training in the respective languages will be provided.

The idea behind establishing and equipping the SALiS-labs for science teacher training is to transfer already existing strategies from the EU partners in the use of lab equipment for promoting more effective strategies in science learning via students' inquiry-based lab-work in school science. I.e., strategies are implemented to base student active lab-work on low-cost lab techniques. Such techniques use everyday-life equipment on no or low costs for conducting experiments in science classrooms (Figure 1). The use of everyday-life equipment is combined with micro and half-micro approaches to reduce costs and demands for waste disposal, and the use of chemicals with low potential to be harmful or environmentally dangerous. Low-cost experiments are used as a strategy to allow for more student experimentation in science classrooms also under less well equipped conditions in schools in central and Eastern Europe. Thus, strategies are implemented allowing the teachers later on in their schools to do students' lab-work under low costs, with low risks, and aiming an environmentally friendly waste treatment (Poppe, Markic & Eilks, 2011).

Figure 1. Example or a low cost experiment developed by equipment form medical technology in the case of the Hofmann apparatus for the electrolysis of water. Low cost equipment (left) costs less 1 Euro, traditional glassware (right) is about 70-100 Eur.

IMPLEMENTATION

SAliS aims on creating the foundation for upgrading science education in many schools to a better level required for supporting the technological and innovative development of the society. Through the implementation of the training modules into pre- and in-service teacher training in all partner institutions the dissemination will become broad and sustainable.

SALIS aims on raising the qualification of staff for in- and pre-service teacher training courses concerning the SALiS philosophy by providing them specific trainings, but also by sharing experiences in good practice during placements in the partner institutions. Therefore, different training sessions have been organized by the partners from within the EU, in Limerick, Ireland, and Berlin, Germany. Staff members from the Central and Eastern European institutions were able to participate. The participants learned about good practices in pre- and in-service teacher training practices for future application of the skills and knowledge to the development of the curricular framework, course syllabi, lists of the experiments and lab equipment within their countries.

The SALiS Labs have been established in Moldova and Georgia. In Israel, partner institutions have enhanced their existing laboratories to suit the goals of SALiS better. The laboratories have included both more traditional equipment and that intended for training for the use for the low cost experiments in teaching.

Additionally, training courses for the teacher trainers and supporting laboratory staff from the beneficiary countries were launched. After an initial meeting with training sessions in spring 2011 in Bremen, respective one-week trainings were now made available in Georgia, Moldova and Israel during autumn 2011 driven by the whole SAliS consortium. Step by step the number of persons involved is raised by involving student teachers into the project to become part of the process of SALIS curriculum development and implementation through MA and PhD studies.

Via the curriculum development and exchange process, implementation of the SALiS training modules also takes place in pre- and in-service science teacher education within the participating institutions from the EU-countries. For this purpose, SALiS offers a collection of good practices, established science teacher training modules and builds up an international platform to transfer and further develop respective approaches, materials and techniques (Figure 1).

Figure 2. The SALiS web platform (www.salislab.org)

The project is funded by the EU in the framework of the TEMPUS IV program: ##511275-TEMPUS-1-2010-1-GE-TEMPUS-JCPR (Agreement, 2010-33821/001-001).

TOWARD A THEORETICAL EXPLANATION OF THE INTERPLAY BETWEEN THE COLLECTIVE AND THE INDIVIDUAL DYNAMICS IN PHYSICS LEARNING

Olivia Levrini[1], Paola Fantini[2], Marta Gagliardi[1], Giulia Tasquier[1], Barbara Pecori[1]

[1] Department of Physics, University of Bologna, Italy
[2] Liceo Scientifico "A. Einstein", Rimini; PhD School, Anthropology and Epistemology of Complexity, University of Bergamo, Italy

Abstract: The paper concerns the analysis of a successful classroom experience where the students made evident progress in appropriating physics knowledge according to personal approaches. The data refer to the implementation of a teaching proposal on thermodynamics in a class of 20 students (17 year-olds) of a scientifically-oriented secondary school in Italy.
The main result of the analysis is the construction of a definition of appropriation, able to act as operative tool for recognising whether students appropriate physics in real classroom contexts.
The study is methodologically framed within the Design Studies. According to such a framework, the paper, although empirically-based, is theoretically-oriented: it is the first step of an iterative process aimed at developing a "humble theory" for explaining when, how and why appropriation is triggered and supported in real classrooms.

Keywords: Teaching/learning science, Design Studies, Thermodynamics, Secondary school level, Appropriation

RESEARCH FRAMEWORK

Background, purposes and research questions

Within European science education research, a great effort has been made in producing models ("sets of principles") for orienting the design and implementation of teaching proposals effective in promoting engagement and deep understanding in physics [e.g. the model of Educational Reconstruction (Kattmann et al., 1996); the model of Discipline-Culture (Tseitlin, Galili, 2005); the model of Longitudinal Development (Guidoni, 2004)].

Most of the models elaborated so far within science education operate at heuristic level: they act as "frameworks for action" (diSessa, Cobb, 2004). A framework for action is intrinsically and self-consciously heuristic. The purpose of a framework for action is to provide some useful foci and directions for the design of curricula or learning environments. However, because frameworks for action may involve multiple, diverse design elements and plans (some of which may have inexplicit underlying assumptions), frameworks for action are not themselves "theories of teaching and learning" that can be tested or falsified. The results of a research study are iterative in nature, and often involve making explicit and gaining a better understanding of the initial choices made by intuition or guess-work and guided by previous design experiences. In spite of the good practices documented in plenty of research papers, the heuristic level has two implications that represent barriers for making progress in developing our current understandings:

- *the proliferation of models*, because of the weakness of heuristics in testing the real held of a model and in comparing different models on the basis of their grip on reality.

- *the inability of the models of establishing "where we are"*, proved by the difficulty of exporting a model out of the research group where it is designed.

The Design Study (or Design Experiments) methodology provides important indications for promoting the development of theories within science education. The theory to which a Design Experiment aims is said "humble" since, unlike a grand theory or orienting framework ("set of principles which identify family resemblances and core values"), it has to be specific enough to be accountable to the activity of design. The theory must do "real work" for improving instructional design (Cobb et al. 2003; Tiberghien et al., 2009).

The paper concerns a theoretically oriented analysis of data collected during the implementation of a teaching proposal on thermodynamics in a class of 20 students (17 year-olds) of a scientifically-oriented secondary school in Italy.

During the implementation, the students made evident progress in finding out personal approaches for appropriating thermodynamics as they took part in the teaching/learning dynamics of the classroom.

The study is the first step in the process of developing a humble theory for explaining *how, when* and *why* individual process of appropriating physics knowledge are triggered and supported by collective dynamics managed by the teacher. In particular, according to the Design Studies, the data analysis we will present for showing *what works* will be underpinned by the concern for arguing "*how, when* and *why* it works, and by a detailed specification of *what*, exactly, *'it' [appropriation] is*" (Cobb et al, 2003).

To sum up, the study has been developed in order to answer the following research questions:

RQ1 - How can the word "appropriation" be defined so as to become an operative tool for recognising and evaluating the effectiveness of a teaching/learning experience (*What "appropriation" means*)?

RQ2 - What factors (features of the content knowledge reconstruction, collective activities, learning environment, mediation action,..) trigger and support individual processes of appropriation *(When, why and how appropriation occurs)*?

Choices at the basis of the educational reconstruction of thermodynamics

The teaching proposal on thermodynamics implemented in the class was designed so as to shape the learning environment as *a properly complex territory* (Levrini et al., 2010). At the basis of the notion of properly complex territory there is the idea that some forms of complexity in physics contents can be transformed into *productive complexities*, i.e. complexities that allow learning environments to be, besides intelligible, rich enough to enable each student to reach deep understanding and to exploit her/his cognitive potential.

The forms of productive complexity, implemented in the thermodynamics path, are:

(1) *Multi-perspectiveness:* the same contents have been analyzed from different approaches - the macroscopic and microscopic ones - treated consistently as two different models;

(2) *Multi-dimensionality:* a critical-philosophical reflection has been developed on the peculiarities of the two approaches through specific activities (questionnaire, discussions);

(3) *Longitudinality:* according to our idea that learning physics is a continuous process of widening, refining, revising knowledge already acquired, the thermodynamics ways of modeling systems, processes, interaction have been systematically compared with the models used in the theories previously studied (classical mechanics and special

relativity).

RESEARCH DESIGN AND METHODOLOGY

During the activities we collected data from different sources: written tasks (quantitative and qualitative problems on key concepts, including problems known as puzzling from the research in physics education); audio-recording of lessons; students' notebooks; notes of a Master student (GT, an Author) observing the classroom activities; questionnaires stimulating critical-epistemological reflection; video and audio recording of classroom discussions about the issues raised by the questionnaires; audio-recorded individual interviews to 10 students conducted at the end of the whole work; audio-recorded interview to the teacher and discussions with her. Since we could not complete 2 interviews because of time constraints, only 8 out of 10 have been taken into account for the analysis.

According to the Design Study methodology, we organized the research as follows.

RQ1 (*"What appropriation is"*)

Phase 1 – Working out the first operational definition of appropriation

In this first phase we focused the analysis on the data related to 5 students: their semi-structured individual interviews; their answers to questionnaires on a critical-epistemological reflection; their contributions to classroom discussions.

The 5 students were chosen on the basis of three criteria: our impression they could represent interesting cases for studying appropriation; the richness of their interviews; their being representative of the class (3 boys, 2 girls, with different levels of performance in physics and different roles within the classroom dynamics).

The data concerning each student were selected and re-arranged so as to draw "the student's profile". In order to make the 5 profiles comparable, all of them were constructed following the same steps: *i)* to pick up the *central idea*, if there is one, around which the student, during the interview, develops her/his discourse; *ii)* to see if and how such an idea is developed along the interview; *iii)* to reconsider the classroom discussions and the answers to the questionnaire in order to check if there is a relationship between the student's position during the interviews and what appeared in the previous activities.

The profiles' comparability allowed the operational definition of appropriation to be grounded on common features of students' discourses.

Phase 2 - Testing the definition

The definition of appropriation was tested against 3 other interviews in order both to refine it and to evaluate its operational power in "making invisible visible" (Strauss&Corbin, 1990). The 3 interviews seemed indeed, at the first overview of the data, cases of non-appropriation.

RQ2 (*"How, when and why appropriation occurs"*)

In order to start searching for an answer to RQ2, we abstracted, from the specific context, the first hypotheses about the structure of an humble theory, pointing out new foci of attention for designing a second level of the experiment within an iterative design.

DATA ANALYSIS AND RESEARCH FINDINGS

RQ1 – Phase 1: Data analysis and findings

The first main evidence which comes out from the comparison of students' profiles is the variety of the central ideas around which they developed their discourse (cfr. Table 1).

Table 1: *Central ideas around which students' discourse runs*

Michele	The Curiosity for "how things work"	"*I like Physics because it explains how reality works, so to say, I'm very curious about how objects work and natural events"*.
Matteo	The pleasure of speculating, in particular on the philosophical distinction between "being and becoming"	*"I believe that […] it is fundamental to build a basis and to speculate on how theories are found, how concepts are elaborated. These concepts will certainly last longer than formulas."*
Chiara B.	The pleasure of understanding by exploring and testing different points of view or perspectives	*"It may be more complete to try to analyze a phenomenon, or whatever is around us, from two different points of view rather than from one […]. It widened my view"*
Lorenzo	The need of searching for a unified consistent framework for deep understanding	*"One can see that everything is integrated, it is not divided in topics each with its own laws, instead everything can be connected, unified; the argument becomes wider, more uniform"*
Chiara C.	The fascinating search for "not obvious details that are usually taken for granted"	*[I like physics since] "obvious things are not taken for granted".[Of thermodynamics I like] "that it made me notice something I had not noticed before."*

The other very important evidence is the students' personal way of talking about temperature, since it was evident that they focused their attention on those features of temperature that were more meaningful to them.

Michele, for example, according to his general perspective, focused his attention on the temperature gradient because this is what makes engines work: "*Different temperatures are necessary…, only with different bodies with <u>different temperatures we can have a cycle and work</u>; different temperatures induce a heat exchange – we can call it so*."

Matteo, instead, focused his attention on the distinction between *ΔT* and *T*, because he saw, in this distinction, the philosophical difference between becoming (change) and being (a state): "*[I think that] Q=mcΔT is <u>becoming</u> […]… there is a change, that means everything is not stable and everything is not being […] the first relation [PV=nRT] is <u>being</u> because […] [there is] absolute temperature T, that doesn't change."*

Thanks to the construction and the comparison of the profiles, the following *features* of students' discourses can be recognised as signals they did appropriate:

a) the discourse is developed, around one key-idea, *consistently* along the whole interview;

b) the key-idea allows the formulation of arguments *on-task*, i.e. arguments which allow aspects of thermodynamics to be selected and meaningfully linked one to the other;

c) the keywords, around which each student constructs her/his arguments, reveal personal engagement, by being *genuine* and *emotion-laden*;

d) the argumentation is *thick*, i.e. it includes elements belonging to a meta-cognitive and/or epistemological dimension;

e) the specific approach to disciplinary knowledge is *not occasional* (it can be traced back to the student reactions in different classroom activities).

The acknowledgment of these features allowed us, finally, to formulate an operational definition of appropriation: *A personal process of content knowledge transformation that* *leads disciplinary knowledge itself* (feature b) *to be a consistent* (feature a) *and personal reconstruction of physics "signed" by the students*, where "signed" means that:

- the voice of the teacher is not present (feature c);
- physics content knowledge is assumed within a personal broad path to knowledge that goes far beyond the mere aim of learning thermodynamics (feature d, e).

RQ1 – Phase 2: Data analysis and findings

The 3 interviews against which we tested the operational definition of appropriation could appeared cases of non-appropriation because of:

- the lack of an evident personal idea around which student's discourse runs.
- the common "flat" sound of their ways of talking about physical concepts (*"In classroom, we have done…", "we have introduced the concept of temperature by…", "I remember that we had…", or "I don't remember if…");*
- the same strategy of talking about physics by going through, chronologically, the classroom activities.

Instead, the finer analysis we could carry out by applying the definition of appropriation shows that only one interview is an evident case of non-appropriation. Another interview reveals not only that the student appropriated thermodynamics, but also that appropriation was particularly difficult to be recognized because of a "natural", spontaneous cognitive resonance of the student with the inner physical language and its formal structure. The last interview shows that the student resonated with the global sense of the work, but she seemed to be still inside the process of searching for her own approach to learning.

To sum up, following the Design Studies methodology, this first part of the study allowed us to construct a definition of appropriation which is *operational* in two senses: *i)* it includes the indication of what *observable features* must be searched in students' discourses for recognizing appropriation; *ii)* it is *effective* for recognizing appropriation also in cases where it is not evident.

RQ2: Data analysis and findings

In order to start the iterative process aimed at answering RQ2, a theoretical move is needed. In analogy with what happens in the physics of complex systems, the kind of humble theory we have in mind is shaped as a dynamical model comprised of:

a) boundary conditions, i.e. those context conditions which make the learning environment suitable and fruitful for triggering and supporting appropriation;

b) a dynamical mechanism lying at the back of the process, i.e. a mechanism enacted and managed by the teacher in order to make *individual cognition, collective dynamics* and the *disciplinary knowledge* resonant with one another.

Good candidates to be boundary conditions

In this specific experiment we see three features of the learning environment that appear good candidates to act as fundamental boundary conditions. They are: *i)* an appropriate content reconstruction where forms of productive complexity are implemented; *ii)* individual attitudes, habits and skills; *iii)* established classroom norms. More specifically:

i) Multi-dimensionality and multi-perspectiveness of content reconstruction acted, reasonably, in a fruitful way for encouraging appropriation since they opened both a plurality of contexts where the same concepts could be applied, and a plurality of points of view through which the students could take inspiration for finding out one's own. In other words, multi-dimensionality and multi-perspectiveness probably are responsible for opening, in the experiment, a suitable *space of possibilities* for making thermodynamics resonate with a plurality of cognitive styles and intellectual interests.

ii) The individual attitudes, habits and skills, that we recognised as particularly evident in those students who appropriated thermodynamics, are:

- the ability of recognizing, in the conceptual scenario, a space for multiple possible paths for understanding;
- the ability of moving back-and-forth from local details to global views;
- the emotional disposition to taking care and accountability of their learning and to venturing their guess for anticipating where the various paths for understanding can lead.

In the discussions with the teacher, she stressed both her attention in fostering such attitudes and skills, and the inner difficulty met by secondary school students:

> *"Very often I say to them: 'Try, try to imagine, to anticipate your mind what will happen if you take one way or ano r one… or a strategy of thought.' […] Young students are more and more fixed i a present dimension 'here and now'. […] I always make it very explicit that playing in the future is a VERY DIFFICULT task, because the rules of the scientific game are well defined and severe and, at the end, not all the ways work (unlike in analyzing a poem, where every route that makes sense to you HAS, somehow, a sense). They have to try for themselves, not for me. This game is very fruitful for managing the anxiety due to learning science and for testing one's own emotional world. They feel much more quiet and relaxed if you tell them that."*

iii) The established classroom norms that reasonably acted in a fruitful way for triggering and supporting appropriation are the following:

- *students' trust* in teacher's attitude of letting them freely play with their ideas (suspending judgement);
- distributed awareness that *each student could and had to provide a contribution* to the collective dynamics.

> *"When students are trying to play with their ideas, it is obvious that I have to suspend the judgment. I tell them that it is a difficult game but that it is worthwhile for them, for their growth. So I have to respect it… I have to be coherent with the message I want to pass… […] My idea is that THEY have to assume the accountability of that. They do not have always to search my approval. If they feel comfortable with their stories, the stories are ok. I only have to help them to respect the constraints posed by physics. This is not easy, but I do believe this is our role as teachers."*

Dynamical mechanism of mediation

Once boundary conditions are satisfied, our hypothesis is that a specific dynamical mechanism of mediation is needed for triggering and supporting appropriation; a mechanism enacted and managed by the teacher in order to make *individual cognition, collective dynamics* and the *disciplinary knowledge* resonant with one another. The discovery of such a mechanism is maybe the more challenging and demanding aim of our proposal of developing a humble theory. We are indeed looking for a description of the mechanism that is specific enough for explaining *how* and *why* teaching fosters and supports personal appropriation, but also not so specific to force different teachers to change their teaching styles.

The next step of the research will be the analysis of data we have already collected in three further experiences realised by two “new” teachers (one of them indeed implemented the same proposal, during the same period, in two different classes). The three experiences share with the experiment analysed here the kind of upper secondary school (“Liceo Scientifico”), age and socio-cultural context of the students, the strong involvement of the teachers in their work. What makes however these data particularly interesting is that one experience, out of three, was unsuccessful: not only appropriation did not occur (with only few exceptions), but also the forms of complexities seemed to play a counter-productive role in fostering basic understanding. A further element of interest is that the unsuccessful experience is one of the two experience realised by the same teacher.

This specific situation will allow us to treat the analysis of the boundary conditions somehow independently of the dynamical mechanism of mediation: being, indeed, the teaching proposal and the teacher the same in a successful and in the unsuccessful experience, we expect to find different boundary conditions responsible for the different reaction of the two classes.

FINAL REMARKS AND IMPLICATIONS FOR RESEARCH

Appropriation is chosen, in this research, as the core idea for recognising whether a teaching/learning experience in a real classroom is successful. Appropriation includes more than deep understanding: it implies that each student situates her/his understanding within a wide personal project of intellectual and emotional growth, according to her/his cognitive style and cultural interests. In the study, an operational definition of appropriation has been built and tested against complex data. We have moreover tried to extract, from our experiment, the draft structure of a humble theory aimed at explaining when, how and why appropriation is triggered and supported in a real classroom. According to the Design Studies methodology, the last results represent the new foci of attention for designing and analysing further experiments within an iterative design.

TEACHING AND LEARNING SEQUENCES FOR THE STUDY OF ELECTRIC ENERGY AT PRIMARY SCHOOL

Dulce María López-Valentín[1], *María Teresa Guerra-Ramos*[1] *and Carmen Mayela Rojo-Camarillo*[2]

[1]Centro de Investigación y de Estudios Avanzados, Unidad Monterrey, México.
[2]Escuela Primaria Carlos Maldonado, Apodaca, Nuevo León, México.

Abstract: In this paper we report the design of an implementation of a teaching sequence of energy and electricity. This sequence was designed following the principles proposed by Sanmartí (2002). A voluntary female teacher helped to our sequence in her 6th grade primary classroom. Her students were aged 10-11. We collected students' productions to be analyzed. From the data obtained, we concluded that our methodology has stengths and weaknesses. We recognized that our teaching sequence has the adequate motivational dimensions and the social significance (contextualization). The whole group showed a 100% good classification of materials and the students succeed building by their own a list of safety rules for an electrician. The weak point was the final evaluation, only 20% built a correct map. The results were not conclusive because we assume that students managed this tool.

Keywords: electric energy, energy, teaching and learning sequences, primary school.

BACKGROUND

The energy concept is one of the most important ideas of science, independently of the discipline which study it: Physics, Chemistry, Biology, etc. At the same time, it is one of the most abstract concepts known and its complex character has intrigued a good number of researchers for more than a few years and has generated many different research areas (Saglam-Arslan, 2010).

At present the education of the concept of energy has started at primary school (Spain, Mexico, Chile, United Kingdom, Malta, etc.). In spite of some researchers that do not agree with its introduction at this stage of formation, Warren (1982) stayed that this concept does not being taught until the students have acquired a high level of abstraction in their reasoning. While Solomon (1983) and Trumper (1993) agree that the teaching of this concept must begin as soon as possible. As can be seen, in the international literature we find positions against or in favour of the introduction of this concept in primary school.

Nowadays, in many developed or not developed countries this concept is taught to early age. Its study is associated with environmental problems which concern to all of us (Rizaki & Kokkotas, 2009) and our country is not the exception.

Designing teaching sequences is a complex activity due to the relationship between knowledge, learning and teaching without forgetting the institution in which the teaching and learning activities takes place (Buty *et al*. 2004).

FRAMEWORK

According to Méheut & Psillos (2000) a Teaching-Learning Sequence (TLS) is used to denote the close linkage between proposed teaching and expected student learning as a distinguishing feature of a research-inspired topic-oriented sequence. A TLS is both an interventional research activity and a product, like a traditional curriculum unit package, which includes well-researched teaching-learning activities empirically adapted to student reasoning. On the other side, recent studies indicate that the most successful TLS are those in which the teacher engages the students' thinking on the topic and produces a sequence that achieves a higher interest and satisfaction in their students.

A variety of TLS's topics have been studied, such as: students' conceptions, features of the scientific domain, epistemological assumptions, learning perspectives, current pedagogical approaches and features of the educational context (Méheut, 2005). Despite this variety, Lijnse & Klaassen (2010) have stated that in the international research literature little information has been published about TLS.

These were some of the reasons which motivate us to share this study concerning the teaching of electric energy at primary school, because almost all the times communication is also made more difficult by the fact that the teaching materials developed are mostly only available in local languages. If they are published at all, details about them can often only be obtained from publications in local journals aimed at teachers.

For the design of this sequence we follow Sanmartí TLS proposal (2002) which includes these four steps: exploration, introduction of new points of view, synthesis and application, and generalization. In this model the TLS planning is organized according to the teaching purpose going from the simple to complex ideas and from concrete to abstract ones.

This TLS at a medium-level (according Kariotoglou and Tselfes 2000) has being designed for the following teaching purposes:

1. To explore the students' beginning ideas of the energy and electric power concepts, bearing their experiences and daily contexts;
2. To present the electrical closed circuit as a necessary system to the electric energy study by introducing the electrical characteristics of different materials (conductors and insulators);
3. To introduce the idea of energy transfer and transformation for the study of the production of electric power, fundamentally the produced on a large scale in the electric power stations, and its employment to obtain other types of energy;
4. To support the students in order that they identify the technological applications of the electricity, emphasizing the ideas of social relevancy as: rational and efficient use of the electric power, rational use of natural renewable resources, environmental problems, communications and safety measures.

PURPOSE

The aims of the present study were:

1. Does Sanmartí TLS model work to teach electric energy at 6^{th} primary level?
2. What are the advantages and disadvantages that the teacher observes during the TLS?
3. How students progress in the understanding of electrical energy?

The study was part of a larger programme aiming at the introduction of innovative ways of teaching and learning science in primary school.

RATIONALE

According to the new curriculum for basic education in Mexico (SEP, 2009), one of the competencies that is claimed students acquire along their primary instruction is the "competition for living together" which implies a good relationship with others and with Nature, that is why it is considered important that a student, at the measure of his/her intellectual capacities, should learn why energetic resources are limited and how and why he/she must take care of them to guarantee a sustainable future. To contribute to this idea we propose the design of a TLS for the study of electric energy at primary school using a macroscopic model with a constructivist approach.

METHODS

30 Mexican students about 10-11 years old participated in the implementation of the TLS. The sequence took place for an hour and a half per day. Over a 2-week period, in the usual form groups and in the normal timetable. The TLS has the following stages:

a) *Exploration*, which includes: choosing words and making sentences using the energy concept, exploring the beginning ideas about energy and electric energy and making a list of appliances of daily use;

b) *Introduction of new ideas*, such as: introduction of the energy concept, types of energy, as well as its transference and transformation; observing some phenomena and applying the energy concept and its transformation; making an electrical closed circuit (a bug model) and classifying materials as conductors and insulators;

c) *Synthesis of new ideas*, for example: energy transformations, calculation of light consumption at home and safety rules for electricity manage, and

d) *Application and generalization*: describing the functioning of an electric power station and building a conceptual map.

Frequent meetings with the teacher taking part in the experiment allowed us to work out a precise protocol and to take into account the students' cognitive skills and the normal operating routines of the school. We defined an accurate protocol with the teacher in order to collect the data during the classes. Each stage of this protocol was supported by a working sheet (five sheets for each student for the whole study). The data were the students' written productions in every tested form and audio and videotape recordings of the teacher's interventions. After the sequence, we assessed a written conceptual map per student to confirm various aspects of the individual model built during the learning sequence.

RESULTS

In general, if we look at the utilization of a sequence as a teaching and/or research tool, several kinds of validation appear. Some methodological approaches aim at evaluating the effectiveness of a sequence by comparing the students' cognitive final stage with their initial one. Other approaches illuminate students' cognitive pathways all through the teaching-learning process. For our work we will only focus if the collected data will assess the global effectiveness of the TLS rather than permit a precise analysis of it.

Analyzing the working sheets produced by students during the sequence and their answers we tried to demonstrate the pedagogical effectiveness of this TLS with regard to the aims of this study.

1. On the whole we conclude that Sanmartí TLS model works good to teach electric energy at 6th primary level. This study is an evidence-based teaching practice which

has proved effective in improving the motivation, engagement and academic and social outcomes.

2. Respect to the advantages of TLS implementation, the teacher feels more confident teaching this concept nowadays. She says that it was an innovative and different way to teach electric energy and she found that the experimental activities are not difficult to do. On the other hand, she said that teaching electrical energy by this TLS is time consuming, reason for avoiding some activities of the TLS.
3. About the students' progress in the undestanding of electrical energy we noticed these indicators:
   a) The whole group (100%) classified materials as conductors and insulators correctly (Fig. 2), previously they built their own electrical closed circuit (Fig. 1);
   b) All the students succeed building by their own a list of safety rules for an electrician using the concepts of conductors and insulators.

Other students' findings when applying this TLS were:

1. About the beginning ideas of the energy concept, a vast majority of the students (80%) associated the word energy with: force, appliances, movement and batteries.
2. With regard to the appliances which consume more energy, they mentioned computer, refrigerator, television and mobile phone.
3. In relation to the introduction of energy transfer and transformation, the types of energy most mentioned (80%) by students were electric (electricity) and calorific energy (heat).

Although this sequence of activities our attention was placed on students, it is noteworthy that the teacher made some changes (we hoped) to the sequence. She changed the time of each activity according to her agenda. She covered all the phases of the model, however, she avoided some specific activities like: calculation of light consumption at home and the functioning of an electric power station. She justified this on the grounds that such activities were complex or time consuming.

Fig. 1. Students building the bug model circuit.

Fig 2. Students classifying materials as conductors and insulators.

CONCLUSIONS AND IMPLICATIONS

The analysis demonstrates stengths and weaknesses of our design methodology. We recognized that our TLS has the adequate motivational dimensions and the social significance (contextualization). The weak point was the final evaluation because we assume that students managed conceptual maps. The results were not satisfactory, only 20% built a correct map.

In science, as in every subject, choices about what to teach, what approach to take to a topic, which aspects to emphasise, the depth of treatment, and so on, are value-laden. They are influenced by our views on why we are teaching science to any particular group of learners, what teaching and learning science means, and why certain outcomes are worthwhile.

The actions and decisions in the classroom belong to the professor, so when someone accepts the adoption of guiadance on how to teach X, we should anticipate and accept, that any particular example of research-informed guidance on 'how to teach X' will not be adopted by some teachers, even if there seems to be quite clear evidence in favour of doing so, because they do not share the values implicit in that guidance (Millar, 2010: p.58).

Demostrating the feasibility or effectiveness of a sequence can be linked to the pragmatic perspective of developing "good educational products".

PERSPECTIVES

To improve this work we will do the next actions:

- To apply in depth the "*developmental research*" as defined by Lijnse (1995): data analysis makes it possible to discuss and improve the effectiveness of teaching-learning strategies.
- To invite more teachers to participate in order to increase the sample (students as well);
- To improve the weaknesses identified by us and by the teacher (which will probably be different);
- To practice conceptual maps with children before TLS introduction (if we decide to use this tool again);

LESSON PLANS FOR STUDENT LANGUAGE HETEROGENEITY FOR THE TOPIC "MATTER AND ITS PROPERTIES"

Silvija Markic[1]

[1]University of Bremen, Germany

Abstract: This paper discusses a collaborative research and development project carried out by science teachers, German as a Second Language teachers, and science educators. The project follows the model of Participatory Action Research in science education. It focuses on the development of teaching modules for early lower secondary science (grade 5, age 10-11) on different topics, including matter and its properties. The teaching modules consequently implement learning content and language as envisioned in the Content and Language Integrated Learning (CLIL) approach. All of the lessons are structured using cooperative and autonomous learning methods. The accompanying research attempts to answer the question of what extent it is possible for pupils to learn science content, scientific terminology and the German language simultaneously as the learners work autonomously in cooperative settings. Data was collected from student feedback questionnaires, cognitive tests, and teachers' feedback and classroom observation. The results show that the lesson plan in question can potentially improve students` learning of science subject matter while bettering the participants' German language skills at the same time. This paper provides insights into the structural elements of the lesson plan and also reflects upon the potential and impact of the cooperative and autonomous learning method selected for the success of the lesson plan.

Keywords: Linguistic Heterogeneity, Science Lesson, Content and Language Integrated Learning, Cooperative Learning, Participatory Action Research

THEORETICAL BACKGROUND

Adult multilingualism is viewed as advantageous in the current, global business world and community. However, multilingualism in the school context is perceived as a source of conflicting issues and deficits (Gogolin, 2005). Ever since the first PISA (OECD, 2006) and IGLU studies (Bos et al., 2003) were published, student linguistic issues have been getting increased attention in political discussions (Hesse, 2008). From the starting point of large, international studies such as PISA, UGLU, etc. we recognize in general that multilingualism (in most cases bilingualism) is primarily a disadvantage, especially among younger learners. In the German context this disadvantage becomes larger for families with migration backgrounds in their history. The majority of German pupils with migration backgrounds only begin to learn German in a standardized, structured fashion after entering primary school at the age of 6-7 years (Brandenburger, 2007). Outside of school, they almost exclusively speak their mother tongue with their families and friends. This translates quite often into students with migration backgrounds achieving overall lower educational levels than native German speakers due to lacking language skills. Reich and Roth (2002) discovered that only in a few cases do bi- or multilingual pupils ever reach the language standard of native speakers. Furthermore, the official school language during lessons, German, is a huge challenge for most such students for two reasons: 1) they often don't know the grammatical rules of either their own spoken language or German (Maas, 2005) and 2) explicit instruction in their mother tongue is not offered in school settings (except perhaps in rare instances where larger minority languages like Turkish or Russian are offered as part of the school curriculum in larger schools. Seehouse (2004) has shown that students have relatively few possibilities to participate actively and productively in regular classroom settings. They experience the new language receptively and have less opportunity to actively use it in order to develop their linguistic competency. Furthermore the undeveloped speech faculties of non-native speakers make content learning difficult. Thus, regular Chemistry lessons turn into a bilingual minefield for such learners. They not only have to assimilate the basic content presented in the lesson, they must also understand and learn the specific language belonging to Chemistry and the scientific endeavor (Leisen, 2004). These students lack the language competencies necessary to communicate and to actively participate the lesson (Söhn & Özcan, 2005; Deppner, 1989) due to this combination. On the other hand, however, Riebing and Bolte (2008) have found that multilingual students have high meta-linguistic competencies in comparison with monolingual, native speakers. This is because they have already been actively exposed to learning more than one language system. Pupils with migration backgrounds proved to be more attentive with respect to the language used in Chemistry lessons. However, answers given by these students also tend to be much shorter and less complex, with less usage of specific, scientific terminology. Additionally, German teachers often do not accept the teaching of German as a foreign language as a necessary goal within their own science lessons. In many cases, they attempt to relegate it to an ancillary position as an issue which should be addressed by other subjects, e.g. in German lessons (Tajmel, 2010).

The achievement of *Scientific Literacy* in all citizens has been the main goal for teaching science at the secondary level since the 1990s. Standards and benchmarks for *Scientific Literacy* have been published worldwide (e.g. KMK, 2005). Furthermore, *Scientific Literacy* states that pupils in school should be able to communicate correctly with different addressees. This includes taking part in public and open discussions about scientific, technological, social, and ecological topics. In order to achieve this aim, it is important that students' linguistic competencies also be emphasized in science lessons. Looking to the situation described above, there is a need to work on this issue.

RATIONALE

This research and development project aims to develop teaching methods and learning materials for linguistically heterogeneous classes, including research on their effect on teaching and learning. A group of science teachers, German as a Second Language (GSL) teachers, and science educators combined to joint develop modules for science lessons. These teaching units focus on beginning secondary school lessons on various topics, e.g. matter and its properties. Consequently, the lesson approach selected and the learning materials developed combine both content and language using Content and Language Integrated Learning (CLIL) along with cooperative and autonomous learning.

Starting from this point the main research question is:

> *To what extent it is possible to simultaneously learn scientific methods, terminology, content matter and the German language as students work in a cooperative, autonomous learning environment?*

METHOD

This project is based on the Participatory Action Research (PAR) design of science education (Fig. 1; Eilks & Ralle, 2002,). PAR is a joint effort between teachers and science educators for curriculum development, educational research, and classroom innovation.

This paper describes the results of a group of five Chemistry/science teachers and three GSL teachers from different schools in the State of Bremen (Germany), who are collaborating with a university researcher from chemistry education. The group meets regularly every three to four weeks and has been developing lesson plans concerning CLIL for about a year now. At the group meetings, changes in teaching practices are proposed, negotiated, and refined so that the resulting structures can be tested and applied in classroom situations before being reflected upon and improved.

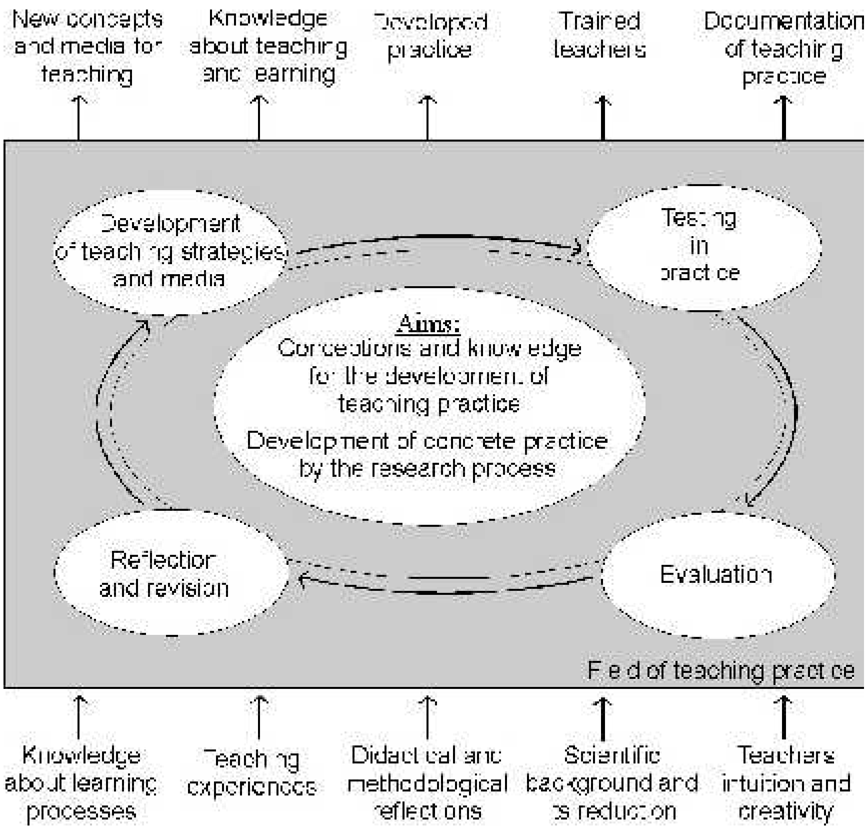

Figure 1: PAR within science education

Four different lesson plans have been developed using this model. The development and evaluation of a lesson plan for “Matter and Its Properties” will be presented in this paper. Table 1 shows an overview of the development and evaluation process. Three of the six groups were continuously accompanied and observed by university researchers. After each lesson was over, the teachers performed self-reflection exercises and documented their progress using narrative reports. These experiences were regularly discussed by the entire PAR group. All of the learning groups took part in a cognitive test and were required to provide student feedback via an evaluation tool comprised of a combination of both an open and a Likert questionnaire.

The lesson plan for “Matter and Its Properties” occurs in two phases: 1) experimenting and 2) exchanging. In the first phase students are divided into two groups: chemists and physicists. Both groups work at stations conducting experiments on the properties of matter. The chemists focus on chemical properties and the physicists concentrate on physical properties. Both groups are structured around a research folder containing helpful materials. The folder is very similar in both cases. The first page lists all the materials needed to carry out the experiments. As a language aid, German vocabulary and definitions are provided, including the definite and indefinite articles for German masculine, feminine and neuter nouns in both the singular and plural forms. This is important, since many German words undergo pronunciation changes and/or receive new word endings in the plural form. Every worksheet begins with a sentence describing the aim of that particular station. Linguistic aids are offered for topics which the teachers in the group viewed as necessary.

In the second phase, the original groups from the first phase are mixed to form new groups. In this next phase, two chemists and two physicists work together. Their job is to exchange the knowledge which they had discovered in their original role with their new partners. They also work cooperatively in an exercise book covering both topics.

Furthermore, the entire lesson plan is supported by laminated “Help Cards” and “Solution Cards” which are available on the teacher's desk in case pupils reach an impasse.

May 2010	analysis of relevant literature; collecting ideas for methods and experiments; first provisional structuring
End of June 2010 (Meeting of the group)	presentation of the provisional lesson plan; negotiating and restructuring the first part of the lesson plan; collecting ideas for structuring the second half
July to August 2010	revising the lesson plan
September to October 2010	testing of the lesson plan in two learning groups; observation of the lessons by one university researcher and teacher self-reflection after each lesson
Mid of November 2010 (Meeting of the group)	reflection on first experiences with the whole group of teachers; negotiating the test and students questionnaires
November to December 2010	testing occurs in another learning group; test and student questionnaires
Mid of December 2010 (Meeting of the group)	reflection in the whole group
January to June 2010	testing in another three learning groups occurs; test and student questionnaires

Table 1: Development and evaluation

SAMPLE

Up until now, the testing and evaluation phases have been carried out using six learning groups (age range 10-11) with a total of 119 students. The lesson plan was tested in different schools in the city-state of Bremen, Germany. All of the schools which participated the study are located in the suburbs of Bremen. They are in parts of the city which have lower social and educational backgrounds, including a high number of residents with migration backgrounds. Table 2 presents some of the characteristics taken from the sample.

Characteristic		Number	Percentage
Sex	***Female***	72	60,5
	Male	47	39,5
Students with a migration background		67	56,8
German not spoken as the home language		45	37,8

Table 2: Sample characteristics

RESULTS

Cognitive outcome: The cognitive test was pre-structured by the teachers according to their personal teaching experiences. The majority of students passed the test successfully, achieving scores of higher than 50% of the total available points. A high percentage of all student groups had scores of "good" or "very good", based on the pre-structured pattern for evaluating the test. A total of 84% of the participants achieved more than 80% of the total points possible. Such achievement was considered to be high and a quite remarkable factor by the teachers.

Teaching methods: Initially, the teachers were reluctant to use autonomous teaching strategies for students with language shortfalls. They expressed considerable fears of leaving such young students alone in a cooperative learning setting. This was not just because of the work on specific scientific topics, but also because the learners would have to simultaneously deal with any difficulties arising from their German language skills. Nevertheless, the teachers were open to experimentation when it came to applying the scheme. After carrying out and reflecting upon the lessons, the teachers’ attitudes changed quite considerably. They were happy with the product they had produced, with the openness of the lessons, and with the overall motivation of their students. This reaction consistently fits the feedback given by the students. The learners judged the lessons to be remarkably good, especially concerning aspects such as help in the verbalization of their own ideas and knowledge, the autonomy of learning, structured cooperation and communication. In particular, they mentioned that the working materials had helped them to better understand the topic both by themselves and within their peer-group. They also agreed that their ability to express their own ideas and results in proper German had grown commensurately.

Process of development: It was easy to observe how the teachers directly influenced the learning process. They considered possible difficulties which they would encounter in the overall approach and suggested appropriate corrective changes. Furthermore, the differing competencies and experiences combined by teachers of science and GSL during the process complemented one another. The teachers did not solely focus only on developing materials which increased the students` scientific knowledge. Instead, they allowed the researchers to sufficiently address and undergird additional factors. These included the simultaneous enhancement of the learners' German and scientific language skills while the pupils were actively engaged in assimilating specific, scientific content knowledge. More details will be given in the full paper.

CONCLUSIONS AND IMPLICATIONS

Even though the process of collaborative development was new for both science teachers and GSL teachers, each group dealt with it in an autonomous fashion, aided by the newly-created teaching materials for the lesson plans. This also held true for the aspects focusing on the teaching of the German language and teaching methods employed. The students were able to cooperatively manage the lesson plan, despite initial doubts expressed by some of the teachers. The expectations of the teachers, which had been set down in the form of a pre-structured test, were exceeded by the pupils, most of whom achieved unexpectedly positive cognitive results. Although this test is limited in scope for judging long-term learning effects, the short-term results provided us with a good baseline for measuring whether students can understand topics on their own, including expressing themselves more easily and correctly through the German language. The initial data seems very promising for implementation of further lesson plans and units which combine the learning of scientific knowledge, German language skills and cooperative learning methods.

Cooperative efforts between teachers of science and those for German as a Second Language seemingly offer attractive possibilities for developing new teaching materials which further linguistic heterogeneity in Chemistry/science lessons. Researchers also had a chance to exchange their personal experiences with linguistic difficulties, knowledge of their students, and any pertinent interdisciplinary information, including methodologies. Furthermore, cooperation between experts stemming from multiple disciplines offers a promising path for creating motivating and highly attractive learning environments. This can bolster science teachers as they attempt to aid their students in simultaneously mastering both scientific content knowledge and German language skills.

THE DEVELOPMENT AND VALIDATION OF A TOOL FOR MEASURING TOPIC SPECIFIC PCK IN CHEMICAL EQUILIBRIUM

Mavhunga M E[1] *and Rollnick M*

[1]University of the Witwatersrand, Johannesburg, South Africa
Elizabeth.Mavhunga@wits.ac.za.

Abstract: The study outlines the development and the validation of an instrument to assess the quality of topic specific PCK, related to the teaching of chemical equilibrium. The instrument uses five topic specific components, namely, learners' prior knowledge, what makes a topic difficult to teach, curricular saliency, representations and teaching strategies. The instrument was administered to groups of pre-service and experienced teachers. The reliability of the tool is reflected to be high as shown by the values for both *person* and *item* indices calculated using the Rasch Statistical Model. For the inexperienced pre-service teachers, the classical measure of reliability (Cronbach Alpha coefficient) was calculated as 0.82, while the person reliability was 0.90 and the item reliability 0.95. For the experienced teachers, the person reliability was also found to be high at 0.91 and item reliability at 0.88; and an acceptable degree of internal consistency (Cronbach Alpha = 0.91). In both cases the item and measured person scores reflected error estimates well inside the conventionally acceptable range of -2 and +2. A further indicator of validity of the tool was the empirically calculated hierarchy of test items found similar to the theoretically predicted pattern for both teacher groups.

Keywords: Pedagogical Content Knowledge, Topic Specific PCK Tool and Subject Matter Knowledge.

INTRODUCTION

Although many studies have elucidated the Pedagogical Content Knowledge (PCK) of both experienced and inexperienced teachers, there is still considerable debate regarding its exact nature. PCK remains an elusive and a tacit construct. There seems, however, to be general agreement that it is a useful and powerful construct, especially for teacher education (Kind. 2009). Much research has been devoted to characterising PCK in practice (see Kind, 2009) and capturing and portraying it (e.g. Loughran, Berry, & Mulhall, 2006), but fewer attempts have been made to assess its quality in science education. Part of the problem in this regard is the lack of agreement that still exists about what exactly is being assessed. In our view, the value of PCK for improving the quality of teaching lies in its topic specific nature, pointing to the need for a topic specific instrument. Thus the discussion herein is part of a larger project, with the specific purpose to design an instrument for measuring the quality of PCK in various selected topics, starting with the concept of chemical equilibrium as illustrated in this paper.

Some research does exist on the development of tools for assessing the quality of PCK, both generic (e.g. Loughran, Berry, & Mulhall, 2006) and topic specific (e.g. Riese & Reinhold, 2009). Work in this area began in the field of mathematics education, but is gaining momentum in science education, exemplified by a paper presented at the 2009 European Science Education Research Association (ESERA) conference (Rohaan, Taconis, & Jochems, 2009) and recently that of Park et al., (2010). As with much of the work quoted above, our interest lies in the development of an instrument that will be easy to administer to large numbers of teachers, with a view to establishing qualitative and quantitative baseline information about their topic specific PCK.

CONCEPTUALIZATION OF THE TOPIC SPECIFIC PCK TOOL

Different models of PCK are employed in the studies cited above but our interest is predominantly in topic specific PCK. To this end we have developed the construct of Topic Specific PCK (Mavhunga & Rollnick, 2011) which as a concept is related to Ball et al's *specialized content knowledge* for teaching (Ball, Thames, & Phelps, 2008). We regard Topic Specific PCK as the understanding that provides the needed knowledge for Subject Matter Knowledge (SMK) transformation in a particular topic. The conceptualization of Topic Specific PCK is premised on the understanding that transformation of SMK is one of the key elements in the establishment of PCK. For teachers with high quality PCK, each topic is transformed as teachers reason about its teaching (Shulman, 1987). When a specific topic is thought through, certain topic specific components of PCK are considered. We identify these as (i) Learners' Prior Knowledge, (ii) Curriculum Saliency (deciding what is important for teaching and sequencing), (iii) What makes the topic easy or difficult to understand, (iv) Representations including powerful examples and analogies and (v) Conceptual Teaching Strategies. All these components are similar to those established in Geddis and Wood (1997). For each individual topic engaged through these topic specific components, the resulting knowledge will be different and specific to that topic.

The Topic Specific PCK tool is thus structured according to the above listed five components of Topic Specific PCK. Each of the components is briefly described below to provide meaning.

(i) Learner Prior Knowledge

Learner Prior Knowledge refers to common students' misconceptions and alternative conceptions about a particular content.

(ii) Curriculum Saliency

Curriculum Saliency refers to the learning of the various topics relative to the curriculum as a whole. It is the understanding of which topics are the most central and which more peripheral. Such understanding enables teachers to judge the depth to which a topic should be covered and hence the amount of time to spend on it.

(iii) What is difficult and what is easy?

The ability to identify gate-keeping concepts, within a concept, that are difficult to understand, triggers dedicated awareness and possible interventions for teaching them.

(iv) Representations

This component refers to a range of subject matter representations including examples, illustrations, analogies, simulations and models. Chemistry teachers, in particular, make extensive use of a variety of representations of their subject matter.

(v) Conceptual Teaching Strategies

Conceptual Teaching Strategies refers to effective instruction strategies for particular misconceptions, known areas of difficulty to learn, or known importance of concepts. It refers to the use of combinations of conceptual principles and rules of a topic as tools to confront potential confusion and misconception.

While the literature makes no claim to a hierarchal order of difficulty among the five components, it is, however, acknowledged from the descriptions, that the component of conceptual teaching strategies encompasses the understanding of the other aforementioned components. This renders the component highest in the order of difficulty. The understanding of common learner prior knowledge may be ranked least difficult as this could be similar to what teachers themselves experienced as learners (Kennedy; 1999).

METHOD OF DEVELOPMENT

Few considerations were made explicit prior to the development process. Like Carlson (1990), we acknowledged that clarity on the aim of the tool is important in order to determine its level. As our aim targets a large base of teachers, it was our view that the tool should adequately accommodate both novice and expert teachers. While this criterion may be viewed as given, its importance emerges in the selection and crafting of test items for the tool. The next issue considered was the care taken to only include test items that measured PCK. In our view, the ability to answer PCK items should require the understanding of specific content knowledge, combined with the knowledge for components of Topic Specific PCK described above. This view implies that the questioned person should have enough content knowledge of a topic in order to recognize the correct application of the pedagogical principle (Carlson, 1990).

Since we had established the conceptual framework of Topic Specific PCK in the earlier study (Mavhunga & Rollnick, 2011), the procedure for developing the tool followed chronologically from (i) confirming the characteristics of the test items fitting the Topic Specific PCK construct, (ii) production of test items, (iii) judgment of items (iv) construction of the instrument (v) piloting and (vi) validation of the instrument. The production of test items was challenging, as it required the strategic blending of specific content knowledge reasoned through the five knowledge components of Topic Specific PCK for various teacher related tasks. Teacher related tasks used in the tool include: assessing and giving feedback to learners, organizing concepts into main and subordinate ideas, sequencing of ideas, analysis for conceptual aspects regarded as difficult, adaptation of representations and making suggestions for teaching strategies for specified cases. The first test items generated were open ended in nature, capturing the responses through written responses. The items were subjected for judgement, to a reference group of 10 members, comprised of senior teacher educators, doctoral students in science education, and physical science teachers. It is in the critical review of the test items that the authors realized that not only should the examinee have topic specific PCK to answer the questions, but so should the examiner. Feedback from the reference team requested further refinement of the wording of the test items, removing ambiguity by adding specifications for the required response and the context of the given scenario, see Figure 1 below:

The format of the expected response specified

The format of the expected response specified

2. What comment would you write on a learner's script who writes:

A reaction reaches equilibrium when the concentrations of the products and reactants are equal.

Figure 1: Test item with specifications for context

Most of the pre and in-service teachers have English as their second language. The refined test items were pre-piloted with a small group of pre-service teachers, and formally piloted with a group of in-service teachers for language and considerations for duration of test. Based on the received responses and the recorded lengthy duration of 75 minutes for both cases, it was decided to frame the open ended questions into semi-closed questions with multiple choice responses to choose from, while allowing an opportunity for explanations and expansion of the choices made. Unlike content test items that may have a singular correct answer, the challenge lay in formulating responses bearing in mind that in teaching there is rarely a single correct way to do something, as shown in the extract in Figure 2 below.

CATEGORY A: LEARNERS' PRIOR KNOWLEDGE

1. What comment would you write on a learner's script who writes:

A reaction reaches equilibrium when the concentrations of the products and reactants are equal.

Response A: No; when a reaction reaches equilibrium it does not mean the concentrations of the reactants and products are equal. The concentration of reactants and those of products are not equal at equilibrium. Sometimes the concentration of reactants is more than that of products and vice-versa. It depends on the type of reaction.

Response B: No; when a reaction reaches equilibrium the concentration of the products and the reactants are not equal. Equilibrium is reached when both reactions proceed at the same rate.

Response C: No; the concentration of reactants and products at equilibrium are not necessarily equal. Each reagent may have its own concentration which is different to the other. What ensures a reaction to be at equilibrium is the rate at which the forward and the reverse reaction occur. For equilibrium to occur this rate must be equal for both reactions.

Response D: None of the above

Choose your response, and use the space below to expand on your choice.

Figure 2: Sample test item from the topic specific PCK instrument

Specific content areas covered by the tool on chemical equilibrium include: closed and open systems, dynamic nature of chemical equilibrium, equilibrium constant, disturbance of chemical equilibrium and the misapplication of the Le Châtelier's principle.

To score the Topic Specific PCK tool, a rubric similar to that in Park et al. (2010), corresponding to the five components was developed with each being rated on a four point scale, from 1('limited') to 4 ("exemplary"). The questions in each component were scored singly as an item, so the test comprised 5 items each with a maximum score of 4. A set of criteria for the component, learners' prior knowledge, is shown below in Table 1 as an example.

Table 1: Extract from the topic specific PCK rubric

Limited (1)	Basic (2)	Developing (3)	Exemplary (4)
*No identification, acknowledgement or consideration of student prior knowledge/ misconceptions	*Identifies misconception or prior knowledge *Provides standardized knowledge as definition *Repeats standard definition with no expansion or provides incorrect explanation	*Identifies misconception or prior knowledge *Provides standardized knowledge as definition *Expands and re-phrases explanation correctly	*Identifies misconception or prior knowledge *Provides standardized knowledge as definition *Expands and re-phrases explanation correctly *Confronts misconceptions/confirms accurate understanding

VALIDATION OF THE TOOL

The developed Topic Specific PCK tool was administered to two different physical science teacher groups: a group of 17 pre-service teachers in the final year of their teaching degree qualification, and a group of 10 qualified teachers whose experience ranged from 5 to 20 years.

The responses to the topic specific PCK instrument were scored using the rubric as described above. The rubric scores were peer validated by independent raters and an agreement rate of 80% was obtained. The raw scores were subjected to Rasch analysis, using the MINISTEP software, which entailed transforming them into probability measures that are on an equal scale (Bond and Fox; 2001). The Rasch model provides two reliability estimates, one for *persons* and one for *items*. The *person reliability index* indicates the replicability of person ordering we could expect if this sample of persons were given another set of items measuring the same construct (Wright & Masters, 1982). The *item reliability index* indicates the replicability of item placements along the pathway if these same items were given to another sample with comparable ability levels (Bond and Fox; 2001, p.32). *Validity* in the Rasch statistics model focuses on the idea that the recorded performances are reflections of a single underlying construct. Two indices of "fit" are provided by the Rasch software. One is called infit and the other is called outfit. Infit indices provide a statistic that reflects expectations of responses to item by specific persons. Outfit reflects items that are quite distant from a person's ability level (Boone and Rogan, 2005, p34). Item and measured person scores that fall within the statistic range of -2 and +2 are considered conventionally acceptable, and therefore indicate that the items and the person measures coherently work together to measure a single construct. The results below are analyzed as per the above described measures of reliability and validity understanding.

RESULTS AND ANALYSIS

The Rasch measure analysis reflected high reliability indices for both teacher groups as shown in Table 2 below. The high scores for person and item reliability in both groups indicate that the newly developed Topic Specific PCK tool has a good spread of measures across the continuum scale. That is, the tool is able to measure both low and high Topic Specific PCK measures with reliability. The high reliability indices further indicate confidence in the replicability of the scores with a comparable sample. The degree of internal consistency within the scores as reflected by the traditional statistics measure (Cronbach Alpha (KR-20) is acceptable for both groups. The fit of both the persons' measures and items' measures within the conventionally accepted range of fit indices -2 and +2, is a conventional indicator that the assumption that the tool measures a single construct dimension, Topic Specific PCK in this case, is empirically proven to hold.

Table 2: Person and Item Reliability Indices

Teacher Group	Person Reliability	Item Reliability	Cronbach Alpha (KR-20)	Fit Statistics (t = -2 and +2)
Pre-service	0.72	0.96	0.52	All scores
Experienced	0.95	0.90	0.92	All scores

The Rasch analysis allows the establishment of the difficulty rank order for test items and persons' ability, as shown in Table 3 below. The results show the five components of topic specific PCK were similarly ranked with a slight difference, where the Representation component is ranked almost equal to the Curriculum Saliency component for the experienced teachers.

Table 3: Ranking of components for the topic specific PCK instrument

Teacher Group	Learner Prior knowledge	What is difficult to learn	Curricular Saliency	Representations	Teaching Strategies
Pre-service	7.61	29.74	62.00	100.65	114.28
	<	<	<	<	<
Experienced	10.10	36.32	53.47	57.97	92.14
	<	<	≤	≤	<

The observed small difference may be attributed to the experience that in-service teachers have over the pre-service teachers. This calculated order of difficulty confirms the theoretical expected order discussed earlier. Such an agreement between the empirical and the theoretical expectation further confirms the validity of the tool (Wright & Masters, 1982, p.93).

DISCUSSION AND IMPLICATIONS

In formulating the test items for the Topic Specific PCK construct, it become clearer that, although the focus was not on SMK on chemical equilibrium, enough understanding of the topic was, however, needed as a base. The validity and the reliability indices of the tool have been found to be high and acceptable. Together, they indicate high confidence in the replicability of the newly developed tool. The findings are encouraging at the prospect of the value of the newly developed instrument. The implication further points to Topic Specific PCK being a valid theoretical construct that has been successfully conceptualized. Also, that an instrument to measure its quality quantitatively has been successfully developed and validated. While this study used chemical equilibrium as an example, research on extending the theoretical concept behind this tool to other topics in science is encouraged.

Abstract: Functional Magnetic Resonance Images result from a complex modelling process. Students have then difficulties understanding the meaning of these images, which are often used in the media with a reductionist approach. In a socio-constructivist approach, we offer students the opportunity to change their representations regarding these scientific models by asking them to collaborate at designing brains MRIs with the *EduAnatomist* software.

In this paper, we explore the relationships between students' interaction types, students' designs of scientific images and students' use of the scientific images to communicate. Data collected consists of software screenshots, slides designed by the students and MSN chats. The interaction types are analysed with Mercer (1998) talk analysis criteria. Moreover, we analyse the use of the software modelling parameters and the relevance of selected information to understand the image, to compare students' productions before and after interactions. Our results show that collaborative work needs time and that even if *disputational talk* could enhance the quality of the scientific images produced by the students, *exploratory talk* is strongly linked to collaborative knowledge production.

BACKGROUND, FRAMEWORK AND PURPOSE

Scientific images as cerebral Magnetic Resonance Images (MRI) are often used by the media with a reductionist approach and often support implicit values (Clément, 2001; Molinatti & Girault, 2007). Due to the complex process that goes into designing them, they are difficult to interpret. To design functional MRI (fMRI), scientists evaluate the variations of brain irrigation by measuring the magnetic resonance of each elementary volume unit of the brain (named voxel). They design subtractive protocols, making several measurements with and without the stimulus, and, using statistical tests, determine whether the difference between the two conditions is significant or not, for each voxel. On the fMRI obtained, the statistical values of the test are coded by the colour of the voxel. As a result, fMRI are both a model and a representation of the brain functions. Previous studies demonstrate that students have difficulties understanding the meaning of fMRI (Mafféo, 2007); thus, improving students' abilities to do so is a challenge for secondary science education.

Our research is based on the analysis of the uses of the software *EduAnatomist*, which allows one to design brain MRI images by downloading real data and choosing appropriate parameters. The main purpose of the learning sequence was to lead secondary students to understanding the status of brain fMRI images. We asked them to design fMRI and to communicate with these images. Our hypothesis was that collaborating to design scientific images would lead students to understand that brain MRI are not pictures of reality, but scientific models dependant on the designer's decisions. In this paper, we address the question of the impact of a collaborative work on the understanding of scientific images.

RATIONALE

Scientific images result from a modelling process. A brain MRI can be considered as a model that links theoretical assumptions on brain functioning and empirical evidence, as scientific models are intermediaries between theoretical and perceptual aspects (Bunge,1975; Sanchez 2008). Learning how to interpret scientific images also relates to the relationships between communication and learning, and can be approached by a socio-constructivist approach (Vygotski, 1934). Moscovici has theorized the link between communication and learning with the concept of social representations concerning the social circulation of scientific knowledge. *Social representations* are involved in "*the formative process and orientation process of social behaviours and communications*", but they are also updated during communication (Moscovici, 1961, p307). For this reason, collaborative learning may offer the students the opportunity to change their representations concerning brain functional images as scientific models. Indeed, collaboration implies construction of shared understanding through interaction with others (Dillenbourg, 1999) and thus brings about the co-construction of knowledge (Baker, 2002). Furthermore, many authors state that computer-supported collaborative learning contributes to students' conceptual and epistemological changes (Hakkarainen, 1998; Arvaja & al. 2008).

We coordinated the collaboration between students, which is defined by Arjava *& al.* (2008) as the engagement of participants in coordinated efforts to solve a problem or perform a task together. For Mercer (1996), this kind of interaction is characterised by "exploratory talk". Our research purpose was then to study relationship between students' interaction types (defined with Mercer talk analysis criteria), students' designs of scientific images and students' use of scientific images to communicate.

METHODS

EduAnatomist allows designing brain MRIs by downloading real research data and choosing appropriate parameters (appropriate section concerning each direction of the brain space, significance of the statistical test). During two hours learning sequence, two pairs of sixteen year old students were asked to work together to produce a slide for the school website. This slide included MRIs designed to explain how the brain is activated by 3 different tactile stimulations (for example, stimulation of tongue, foot and index). The collaboration had been previously prepared, using *EduAnatomist* to design and parameter the MRIs for 2 tactile stimulations. Students were asked to integrate this MRI in a slide containing all the information they thought necessary to be understood by other students.

The two pairs interacted by text messaging with MSN, sharing their previous productions for the design of their slide for the school website. Three different kinds of interactions were observed in this experiment: oral and direct interaction within the pairs of students, writing and distant interaction between the two pairs of students and writing interactions corresponding to the written information in the slide they were designing. This paper will focus on the text messaging collaboration phase between two pairs of students. Students were not allowed to communicate directly by showing their computer screens to one another. They had to formulate and explain their choices. Students had to imagine what the school website visitors would know and had to adapt their slides to make the images understandable.

The data that was collected encompasses software screenshots and slides produced by students before the chats, the text of the MSN chats and the slides produced by students during the chat. We quantified and qualified the interactions within the teams and explored theirs effects on the slides produced by students. The duration of the chat, the number of words and the number of interactions in each team were calculated. The argumentation was analysed using Mercer (1998) categories of talk: in *exploratory talk*, statements and suggestions are offered for joint consideration. These are challenged and counterchallenged with justifications and alternative hypotheses. In *cumulative talk* the participants build positively, but uncritically on what the other says. Knowledge is constructed by accumulation. *Disputational talk* is characterized by disagreement, competitiveness and individual decision making.

The modification of the students' productions during interaction was observed by comparing the slides produced before and after the pairs of students interacted. We referred to the learning objectives of the activity, which were the correct use of software modelling parameters to design an image that effectively shows the brain activated areas, and the identification of information needed to understand the image. The first objective was called *scientific value* and evaluated by identifying the number of cerebral areas effectively visible on the image in conjunction with the statistical parameters chosen by the students. The second objective was analysed by observing *caption relevance*, which refers to the number and kinds of caption added to the image. We also looked at what was modified, or not, or planned to be modified, in the slides by the students during chat sessions. Four sets of interaction between two pairs of students were studied in this experiment.

RESULTS

1) Types of interaction

Due to the difficulty in designing the images, the time devoted to chatting was shorter than we had planned. However, 3 groups had a quarter hour chat session (Table 1). Qualitative analysis of the chat sessions shows little argumentation leading to a firm conclusion. Student pairs 7B-8B were not involved in a real collaboration. They disagreed, made individual decisions and didn't work towards a common production (Table 2). Their chat consisted mainly of *disputational talk*. Student pairs 3B-5B (Table 3) were involved in a common task, through *cumulative talk*: they interacted positively but uncritically, saying "Why not?". They just accepted what was said by the others to build their proposition, without any critical thinking.

Interacting students' pairs	1B-2B	3B-5B	4B-6B	7B-8B
Chat's duration (min)	17:58	15:23	01:51	14:00
Number of interactions	21	30	4	19
Total of words	247	234	51	163
Statement without justification	6	1	-	3
Argumentation	5	2	-	3
Type of talk (Mercer, 96)	exploratory	cumulative	-	disputational

Table 1: Quantitative and qualitative analysis of the chats

Student pairs 1B-2B (Table 4) had a richer argumentation, with claims presenting data and explicit warrants (based on Toulmin (1969) argumentation model). Each of their suggestions was critically considered by the other; thus, their chat session shows an example of *co-argumention*. In regards to statistical parameters (the value of which can be chosen on the software within the bounds of two limits) 2B gave his choice, which 1B found too low, showing here a critical position. Then, they constructed together the argument leading to their common choice, one partner giving the ground and the other the warrant before the claim. When they tried to use this parameter, they formulated critical arguments ("can not take 70 ... there is nothing"). It shows that they collaborated to solve the problem (*collaborative talk)*.

7B	*What are your cursors ?*
8B	*inf 30 and sup 100*
7B	*It's not very clear. You must be higher where you put 30, to be more precise*
8B	*No, you choose too high value. Each to their own.*
7B	*No, no, teacher says it to us just now, and for us, it's very clearer*
8B	*Ba.. we don't give a fuck about*
7B	*Come on, start it again !*
8B	*No*

Table 2: Extract of chat between 7B and 8B students' pairs showing disputational talk (Translated from French).

3B	You want to replace command area with command area answering to the stimulation ?
5B	Yes, exactly man
3B	Da why not …

Table 3: Extract of chat between 3B and 5B students' pairs showing cumulative talk (Translated from French).

2B	*Top 32, down 100* (speaking of statistical requirement)
1B	*ok, but there's still quite a bit of error marging*
2B	*Yeah. We must take the same number* (warrant)
1B	*with 70 and 100 it is less important* (ground)
2B	*we take 70* (claim)
1B	*OK ...*
2B	*can not take 70 ... there is nothing ... we must take the same data*
1B	*Yes, we take less then, but should not have too low value… you can still go down, so try with 60 and 50*

Table 4: Extract of chat between 1B and 2B students' pairs showing exploratory talk (Translated from French, brackets for our own observations).

2) Effects of interaction on the students' productions

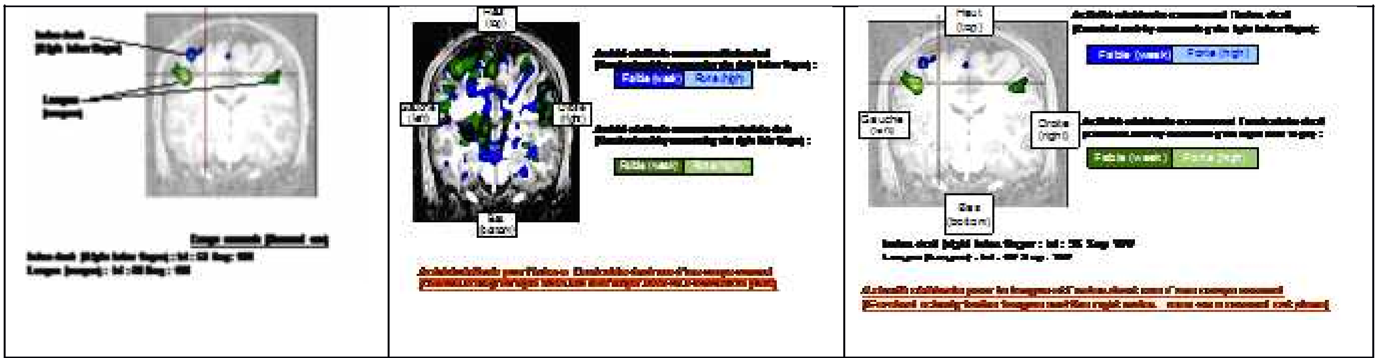
Multiple effects of these interactions on the students' productions were observed. For 3B-5B (Table 5), who had the same scientific value for their production before the chat, the interaction lead to an increase in the caption wealth, after they chose one of their productions.

Student pairs 1B-2B discussed a lot about the meaning of the statistical requirements and tried to produce a common MRI with the same statistical limits. We can notice that they had different scientific values before the chat. 1B selected high statistical parameters and displayed 2 areas, while 2B hadn't been able to find any effective cerebral area, because of its low statistical parameters. We can argue that the fact that they had very different productions at before their discussion lead them to interact more effectively, to criticize each other and to conduct exploratory talk. This was not the case for 3B-5B, who had the same type of scientific value for their previous productions and just performed cumulative talk. They worked on the captions, which were different in their previous slides, 3B's captions being richer than 5B's. The best production was chosen to begin the collaborative work.

Pairs 7B-8B had different types of production before the chat session. The two brain areas involved in tongue and index stimulations were clearly visible on 7B's fMRI, but only 4 elements were indicated in the title and caption (Figure 1). In contrast to this, the scientific value of 8B's production was bad, but the caption was very rich and elaborated. The large coloured areas displayed on 8B's fMRI (Figure 1) were not specific to the studied stimulation, because the statistical parameters were too low. During the disputational talk, 8B refused to modify their statistical requirements, but used 7B's slide to complement their own production, applying their caption on the high-valued scientific image produced by 7B. 8B didn't inform 7B and didn't send them the result. They just took advantage of the interaction for their own selves, in a sort of competitive way.

	Exploratory talk		Cumulative talk	
	1B	2B	3B	5B
Cerebral regions Statistical parameters	2 high	0 low	2 medium	2 medium
Caption elements	5	6	7	4
Discussed during chat	Statistical parameters		Caption	
Conserved elements	_		3B production	
Modified elements	Statistical parameters		Caption (2 elements added)	
Final production	Increase scientific value		Increase caption wealth	

Table 5: Analysis of students' slides



7B slide	8B slide	7B slide modified by 8B

CONCLUSIONS AND IMPLICATIONS

One way to foster the understanding of MRIs can be the use of MRI visualization with software like *EduAnatomist*, which enables students to see the consequence of their choices of statistical parameters on the generated brain images. However, statistical thinking is difficult for students and concepts such as statistical tests or statistical comparisons must be understood before designing the images. The difficulties of understanding MRIs are also linked to the difficulty of visualizing the brain volume with plane sections and in transferring numerical statistical significations into coloured graduations. Therefore, it would be important to adapt the interface of the software to the students' level of knowledge and to the pedagogical objectives of the activity (Monod et al, 2011). Moreover, our experimentation brings to light the importance of the time devoted to implementing a collaborative work, especially if the concepts to learn are something as complex as the modelling of cerebral activity in functional MRIs.

Designing this type of scientific image by distant collaboration leads pupils to formulate and explain their choices. Within the few examples studied, we observed that pairs of students having different types of productions before the chat interacted with more criticism. If disputational talk can enhance the quality of the scientific images produced by the students, exploratory talk is linked to collaborative knowledge production and must be promoted. How can we foster collaboration and exploratory talk? Firstly, it is clear that much time is needed. Secondly, the pairing of students can be based on their previous productions (for example, associating students having different types of scientific value and caption value productions). This corresponds to the adaption of the script of an activit,y as promoted by Arvaja *et al*. (2008) and Dillenbourg & Jermann (2006). Structuring the students' communication and using tools to do so can also promote exploratory talk (Arvaja *et al*., 2008; Jermann *et al.*, 2004).

Designing scientific images for communication with peers is also a way to bring the students to reflect on the information needed to understand the image. In our experiment, students had to imagine what elements the school website visitors would know and had to adapt their slides to make the image understandable. In doing so, after setting the statistical parameters of the fMRI, they could perhaps realize that the fMRIs significance depends on their construction and modelling parameters, which leads to a better epistemological approach in regards to these scientific images.

Fostering a better understanding of MRIs is important, as the media, with a reductionist approach, puts forth disputable assertions in regards to these images. Further studies must be conducted to demonstrate that our modelling-based approach can change fMRI social representations. However, the use of software such as *EduAnatomist,* which implement scientific activities that are close to the real work conducted by scientists, is important. It offers to the students the opportunity to understand the core functioning of science.

PEDAGOGICAL LINK MAKING: A METHODOLOGY OF ANALYSIS OF TEACHING AND LEARNING SCIENTIFIC CONCEPTUAL KNOWLEDGE

Eduardo F. Mortimer[1] *and Phil Scott*[2]

[1] Universidadade Federal de Minas Gerais
[2] University of Leeds

Abstract: This paper provides an introduction to the concept of pedagogical link-making in the context of teaching and learning scientific conceptual knowledge. Pedagogical link-making is concerned with the ways in which teachers and students make connections between ideas in the ongoing meaning making interactions of classroom teaching and learning. We draw upon sociocultural perspectives to outline why we think that 'link-making' is fundamental to science learning and consequently to science teaching. We identify three main *forms of pedagogical link-making* and try to find some *pedagogical link-making approaches* associated with each of the three main forms. The resultant *framework* of link-making forms is applied in analysing a teaching sequence taken from a UK secondary school science classroom. Part of this analysis involves identifying specific *pedagogical tools/strategies* and *approaches* which might be employed in the classroom to support link-making.

Keywords: pedagogical link-making; scientific conceptual knowledge; teaching

INTRODUCTION

In this paper we introduce the process which we regard as being central to the teaching and learning of scientific conceptual knowledge, or indeed any other form of disciplinary subject matter: the *'pedagogical link-making'*. The idea of pedagogical link-making has arisen partly from our on-going programme of research on teaching and learning scientific conceptual knowledge (see, for example, Authors, 2003, 2006 and 2010), partly from scrutiny and analysis of relevant sections of the international research literature and partly from reflecting on our own teaching and learning experiences over the last thirty years. Pedagogical link-making is concerned with the ways in which teachers and students make connections between ideas in the ongoing meaning making interactions of classroom teaching and learning.

In this paper, we shall draw upon sociocultural perspectives to outline why we think that 'link-making' is fundamental to science learning and consequently to science teaching and identify three main *forms of pedagogical link-making*. We shall apply the resultant *framework* of link-making forms in analysing a teaching sequence taken from a UK secondary school science classroom and use this analysis as a basis for further reflecting on the key features of pedagogical link-making. Part of this analysis will involve identifying specific *pedagogical tools/strategies* and *approaches* which might be employed in the classroom to support link-making.

THEORETICAL FRAMEWORK

Link-making for teaching and learning scientific conceptual knowledge

The idea that learning conceptual knowledge involves the learner in making links between their existing knowledge and new ideas is a basic assumption of constructivist perspectives on learning (see for example, Larochelle et al, 1998). The same is true for sociocultural accounts of learning where Vygotsky (1987) sees learning scientific conceptual knowledge as entailing a passage from social to personal planes through a process of internalisation. The internalisation step does not involve the learner in absorbing knowledge 'fully formed' from the interactions of the social plane, but involves a process of individual *reconstruction* as the learner makes sense of new ideas in terms of their existing ones. In this way learning or meaning making is regarded as being an essentially dialogic process which involves bringing together and working on ideas.

Thus coming to understand an idea involves bringing into contact new and existing ideas; it involves *making links* between new and existing ideas as we match the speaker's word with a counter word, with the depth and extent of understanding depending upon the number and quality of the links made. Put simply, the teacher must address link-making on the social plane of the classroom in order to support students in constructing similar links for themselves on the personal plane.

In our analysis we shall relate the link-making process with the four classes of communicative approach (Authors, 2003), which are defined by categorizing the talk between teacher and students along two dimensions. The first dimension represents two forms of interaction, dialogic and authoritative, whilst the second dimension involves the distinction between interactive and non-interactive talk. For the first dimension, dialogic communication involves teacher and students paying attention to more than one point of view, more than one voice is heard, and there is exploration or 'interanimation' (Bakhtin, 1981) of ideas. In general terms, dialogic discourse is open to different perspectives. Alternatively, in authoritative communication attention is focused on just one point of view, only one voice is heard and there is no exploration of different ideas. For the second dimension, the talk can be interactive in the sense of involving the participation of more than one person, or non-interactive in the sense of involving the participation of only one person, which is usually the teacher. The two dimensions combine to generate four classes of communicative approach: Interactive/dialogic, non-interactive/dialogic, interactive/authoritative and non-interactive/authoritative.

Three forms of pedagogical link-making

Starting from basic principles of teaching and learning, we have identified three forms of link-making. The first entails making connections between different kinds of knowledge to support students in developing a deep understanding of subject matter. We refer to this as pedagogical link-making to *support knowledge building*. The second form of link-making follows from the fact that both learning and teaching, by their very nature, are played out over a period of time, involving days, weeks, months, years. Consequently, if deep learning is to be the outcome, there is the need to make links between teaching and learning events occurring at different points in time thereby promoting a form of intellectual continuity (Mercer, 2008). We refer to this as pedagogical link-making to *promote continuity*. The key feature of links to promote continuity is that they involve making references to teaching and learning activity across points in time. The third and final form of pedagogical link-making, which we have identified, is rather different in kind to the first two and relates to the different ways in which the teacher makes links to encourage a positive emotional response from students to the ongoing teaching and learning. We refer to this as pedagogical link-making to *encourage emotional engagement*.

THE METHODOLOGY AND THE CASE STUDY

We applied the framework to a particular case, articulating the four classes of communicative approach to different approaches and strategies used by the teacher to promote link-making. The case study focuses on a short sequence of five science lessons with a mixed ability year 7 (students about 12 years old) science class in a state secondary school in a semi-rural setting in the North of England. The teacher is a science specialist with about 20 years teaching experience and is highly regarded in the local science teacher community and is, by any standards, an expert teacher. The aim of the lessons was to provide an introduction to a school science view of four specific kinds of force: tension, gravity, normal force (also referred to as the 'up-push' by the teacher) and friction. The case study focuses on the way in which two of the content themes were addressed in the lesson sequence. These are the 'normal force' and representing forces through an arrow (force vector) notation. The teaching and learning of both of these themes took place over three consecutive lessons.
The lessons were video taped with one camera and the teacher was interviewed after each lesson. We also conduct interview with some of the students after the five lessons. We segment the video in episodes. Our definition of episode is an adaptation of the definition of event in the interactional ethnography tradition. Therefore, an episode is defined as a coherent set of actions and meanings produced by the participants in interaction which have a clear beginning and end and can be easily discerned from the previous and subsequent episodes. Usually this distinct set is also characterized by a specific function in the flow of discourse. Border markers between the episodes include verbal and non-verbal aspects. The contextual cues referred to by Gumperz (1992) include proxemic (related to the orientation between the participants) and kinaesthetic changes (related to gestures and body movements), changes in intonation, emphasis, topic or theme, genre, pauses, etc. These cues permit the precise determination of the frontiers of each episode in the flow of time.
After segmenting the video in episodes and making a map of episodes we qualitatively analyse the episodes trying to identifying all the links made on each specific episode.

RESULTS

For each of the three forms of pedagogical link-making we identify different pedagogical link-making approaches in our date. For the form 1 – *support knowledge building* – we identify the making of links between: 1) everyday and scientific ways of explaining; 2) scientific concepts; 3) scientific explanations and real world phenomena; 4) different modes of representation; 5) different scales and 6) analogous cases. For the form 2 – *promote continuity* – we identify the making of links related to the development of the scientific story and to the management/organisation of the class. These links were made through three different time scales: macro, meso and micro. For the form 3 – *encourage emotional engagement* – we found two main approaches: one which addressed substantive content of the lessons, whether by linking to ideas or by linking to contexts/phenomena, which we called pedagogical approaches; and the other involving strategies of encouraging people to participate in the lesson, which we called generic approaches.

We shall give examples of each of the approaches indicated here and describe how the link-making framework can give evidence of the learning process. It is clear that if link-making is not addressed through teaching then it is unlikely to emerge in students' learning. From this perspective, then, both teaching and learning must involve link-making processes: they are the complementary sides of the same pedagogical coin.

AN INTERVENTION FOR USING MULTIPLE REPRESENTATIONS OF MECHANICS IN UPPER SECONDARY SCHOOL COURSES

Pasi Nieminen[1], Antti Savinainen[1], Niina Nurkka[2], and Jouni Viiri[1]
[1]Department of Teacher Education, University of Jyväskylä, Finland and
[2]Faculty of Health Care and Social Services, Saimaa University of Applied Sciences, Finland

Abstract: Previous research has emphasized the importance of multiple representations for learning and understanding physics concepts. Students should learn to construct multiple representations of physical processes and learn to move in any direction between these representations. For this purpose, we designed teaching material emphasizing multiple representations within the context of forces. The material and short instructions (= intervention) were given to two experienced upper secondary school teachers who were not involved in designing the intervention. They used the intervention material in their mechanics courses in fall 2009 (students *n*=28 altogether). The effect of the intervention on the learning of forces and representations was evaluated using a multiple-choice test Representational Variant of the Force Concept Inventory (R-FCI) as a pre- and post-test. In addition, students' answers to exercises of the intervention material were copied and collected. All lessons were videotaped and the teachers were interviewed after the course. The results were compared with the R-FCI baseline data (*n*=22 altogether) collected prior to the intervention from the same mechanics course taught by the same teachers in fall 2008. Our results suggest that the intervention material was useful for students' learning of the force concept and multiple representations.

Keywords: Multiple representations, mechanics, force, intervention

INTRODUCTION

This study concentrated on multiple representations of upper secondary school physics in the context of Newtonian mechanics. The focus was on external representations (e.g. graphs and vectors) as distinct from internal, mental representations. In the school context, external representations can be seen as communicative tools between a teacher, students and media (e.g. books), and also as cognitive tools when students are working alone, for example, in problem solving. Instead of processing everything internally in their minds, they can create an external representation and thus reduce the cognitive load (Schnotz, Baadte, Müller, & Rasch, 2010).

Multiple representations refer to the circumstances where various representations are used for learning a concept or solving a problem instead of, for example, only verbal and mathematical representations. Multiple representations have many functions in learning (Ainsworth, 1999). They can complement and constrain other representations, and construct a more complete understanding. According to Van Heuvelen and Zou (2001), multiple representations are useful in physics education as they foster students' understanding of physics problems, building a bridge between verbal and mathematical representations, and helping students develop images that give meaning to mathematical symbols. These researchers argue that students should be taught to construct multiple representations and to move in any direction between these representations. Furthermore, studies in physics education research have shown that the representational format in which a problem is posed significantly affects student performance (Meltzer, 2005; Nieminen, Savinainen, & Viiri, 2010).

A natural resource of multiple representations in studying physics would be a textbook, which indeed plays a central role in teaching and learning in Finland (Korkeakoski, 2008). Textbooks have been constantly revised in accordance with the present curriculum. Generally teachers follow the structure of textbooks and they use textbook-based exercises for class- and homework. Finnish students have become accustomed to studying with textbooks. Whilst we are aware that Finnish textbooks draw on standard representational formats used in physics, they do not necessarily offer many exercises that stress the use of multiple representations.

There is some research in science education on how evidence-informed teaching interventions can be transferred to teachers who have not been involved in designing the interventions (Leach, Scott, Ametller, Hind, & Lewis, 2006). As pointed out above, the emphasis on multiple representations in teaching and learning is important for understanding physics. However, we were unaware of any studies in which multiple representations-based teaching interventions are implemented by transfer teachers in upper secondary school. In order to study this we designed an intervention that stressed the use of multiple representations in the context of force and conducted a study concerning the use of this intervention in two upper secondary school mechanics courses taught by two transfer teachers. We hypothesized the intervention could enhance students' learning when implemented by transfer teachers.

The research questions were:

1) How did the transfer teachers integrate the intervention into their teaching without any extra training?
2) How did the intervention affect students' conceptual understanding of force and their ability to interpret multiple representations?
3) What kind of textbook exercises were used from the perspective of multiple representations?

METHOD

Design and experiment of the intervention

This paper mainly describes the intervention and baseline phases of the study, however each phase (Fig. 1) is briefly presented. The intervention material itself was designed during the design phase. The material consists of seven exercises (3–6 sub-items per exercise). These open-ended, paper-and-pencil exercises emphasize the use of multiple representations and guide movement between the representations in different contexts that address the force concept. During the pilot phase, the material was used in an upper secondary school course taught by one of the authors (AS). After the pilot phase we made some improvements to the material. Only the research group (the authors) participated in these three phases.

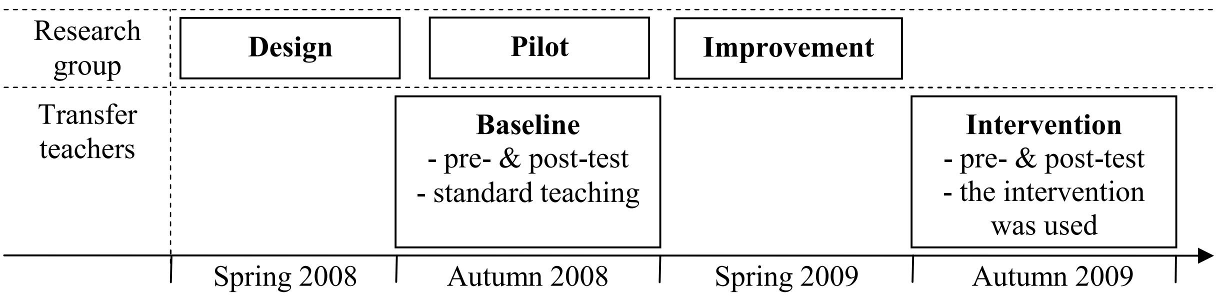

Figure 1. Different phases of the study

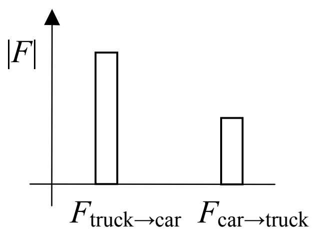
The baseline phase was required to evaluate the influence of the intervention on students' learning. Between the baseline and intervention phases, the teachers remained the same, as did the courses within the same high school mechanics courses. The only difference was that the intervention was not used in the baseline phase and, of course, the different year groups contained different students.

During the intervention phase, we gave the intervention material to two transfer teachers. We did not want to interfere too much with the teachers' plans for the course, hence we only made suggestions about when to use a certain exercise during the course in relation to the content of the course. We did not provide instructions on how to use the material.

Pre- and post-test instrument

For evaluating students' understanding of the force concept and the ability to interpret multiple representations consistently (i.e. *representational consistency*) the Representational Variant of Force Concept Inventory (R-FCI; Nieminen et al., 2010) was used. The R-FCI contains nine *themes* concerning gravitation and Newton's laws in different contexts. Each theme has three isomorphic items (the context and content remain as similar as possible) in different representations. Each item contains five multiple-choice alternatives: one scientifically correct and four incorrect distracters. Figure 2 provides an example for corresponding alternatives of the items of a theme. A more detailed description of the R-FCI is provided in our previous article (Nieminen et al., 2010).

Item #2, alternative (d).



Item #11, alternative (a).

The truck exerts a greater amount of force on the car than the car exerts on the truck.

Item #20, alternative (c).

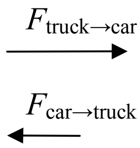


Figure 2. Corresponding multiple-choice alternatives of the items of a theme of R-FCI

The R-FCI was used to evaluate representational consistency. When a student exhibits representational consistency, scientific correctness is not required. Figure 2 shows an example of one representationally consistent answer pattern in which each item has been answered scientifically incorrectly. Of course, if a student answers all three items of a theme correctly, he/she also exhibits representational consistency as the selected alternatives correspond between the items.

The R-FCI score (sum of scientifically correct answers) can be used for evaluating students' conceptual understanding of force. The pattern in Figure 2 exhibits no conceptual understanding: each item has been answered scientifically incorrectly and answering this way does not increase the score. Instead, answering each item of the theme correctly would add three points to the total score. It should be noted that understanding a representation is required to solve a conceptual problem with that representation. Hence the R-FCI score, as a measure for conceptual understanding, is not independent of the understanding of representations. However, there are strong correlations between R-FCI and FCI scores indicating that the R-FCI score is appropriate for evaluating conceptual understanding of force (Nieminen et al., 2010).

Participants and data collection

Both transfer teachers had over 10 years, and therefore extensive, experience in teaching upper secondary school physics. The students (aged 17) were taking their fourth physics course (mechanics, 30 lessons, 45 mins per lesson) in autumn 2008 (baseline courses, *n*=22 altogether) and 2009 (intervention courses, *n*=28 altogether). Each student took the R-FCI as a pre- and post-test. In the results section, we have referred to the schools as School1 and School2, and the teachers as Teacher1 and Teacher2 respectively.

During the intervention phase each lesson was videotaped and the teachers were interviewed after the course. The intervention students' answers for the intervention exercises were collected before the teacher gave the correct answers. We did not, however, get all of the intervention students' answers for all of the seven exercises. The exercises were given at different points during the course and some students were not in school on certain days or did not complete the exercises for one reason or another. In the analysis of the intervention exercises we have included students (*n*=21) who completed 4-7 of the exercises. The baseline students did not complete the intervention exercises at all.

Video-data analysis used Atlas.ti software and PASW Statistics 18 was used for the quantitative analysis of R-FCI data and intervention exercises. To evaluate the conceptual understanding change we used normalized gain (Hake, 1998) defined as the ratio of the actual gain to the maximum possible gain:

$$< g >= \frac{\text{Post - test \%} - \text{Pre - test \%}}{100\,\% - \text{Pre - test}}$$

Normalized gain is independent of students' pre-instruction score of measured variable, useful for the comparison of student groups. Normalized gain can be calculated from class averages (average normalized gain) or single-student scores (single-student normalized gain). This study used the latter for statistical comparisons of student groups and correlation analysis.

RESULTS

Implementation of the intervention

Both teachers used the intervention exercises as homework: They gave an intervention exercise to students as homework and they presented the correct answers at the beginning of the next lesson. Hence, the teaching time used for the intervention was very limited: 7% in School1 and 4% in School2.

There were differences, however, in how the teachers talked through the solutions of the exercises: Teacher2 only showed the correct answers, whereas Teacher1 elicited the correct answers from the students. On the other hand, Teacher2 criticized some exercises and our example solutions. Both teachers closely followed our suggestions as to when to use a certain exercise, albeit that the final exercise #7 was not completed in School2 at all. Most of the time, interaction between students and the teacher was minor or non-existent in both courses and teacher presentation was the dominant activity in class. Teacher2 gave much more time (39% of teaching time) to student work without his involvement than Teacher1 (only 6%).

Text book exercises in the intervention courses

School1 used a different textbook than School2 (School1: Lehto, Havukainen, Leskinen, & Luoma, 2006; School2: Hatakka, Saari, Sirviö, Viiri, & Yrjänäinen, 2005). Each textbook exercise used for class- or homework was analysed. We found that 77% of the textbook exercises in School1 were presented via verbal format (text) only. The other exercises (23%) also included one other representation: a graph, a picture or a table. In School2, 50% of the exercises were in verbal format only, and 48 % also included a graph, a picture, a table, vectors, or a motion map. One exercise (2%) included verbal, pictorial and graphical representation. Many exercises included mathematical markings, such as 7 m/s, but no exercise included equations, for example $F=ma$. This analysis did not concentrate on which representations were demanded for solving the exercises, but only which were presented on the textbook page.

We also categorized the textbook exercises as quantitative (calculations were needed in the solution) or qualitative (no calculations). In this categorization, a certain quantitative exercise may contain some qualitative characteristics, but a qualitative exercise does not contain any calculations. Table I shows that the most of the exercises were quantitative in School1 (81%) and School2 (63%), but these were more frequently employed in School1. The majority of exercises (67%) were quantitative in verbal representation in School1. This was the most general type also in the School2, however less frequent there (39%). Qualitative exercises were performed more frequently in School2 (37%) than in School1 (19%). In particular qualitative exercises which included verbal and one other representation were more common in School2.

Table I. Classification of textbook exercises in School1 and 2. Some of the exercises were expressed via *only verbal* representation and the other exercises via verbal and one other representation (*verbal* +). *One exercise (2%) included verbal and two other representations.

		Quantitative		Qualitative	
School	Number of exercises	Only verbal (%)	Verbal + (%)	Only verbal (%)	Verbal + (%)
1	58	67	14	10	9
2	62	39	24*	11	26

Conceptual understanding of force

On average the normalized gain was higher among the intervention than baseline students in both schools (Table I), but the differences were not statistically significant. However, for all students (School1&2) the nearly significant p-value (.077) and the effect size of .56 suggested that the learning outcomes were better among intervention students than baseline students (medium $d\approx0.5$; (Cohen, 1988).

We studied the students' answers to the intervention exercises and found various misconceptions (e.g. impetus or dominance conception) and errors in the use of representations. We also graded the correctness of students' answers and found that the students' (n=21) intervention exercise scores correlated with students' normalized learning gain (ρ=.50, p=.022). Hence, the R-FCI and intervention material seem to evaluate the same content and skills at least to some extent.

Table I. Normalized gain and standard errors (parentheses) in different student groups. For differences between gain of intervention and baseline groups Mann-Whitney U-test was conducted and Cohen's effect sizes calculated.

	Intervention course		Baseline course		For gain differences	
School	Gain	n	Gain	n	p-value	Effect size (d)
1	.39 (.08)	16	.19 (.10)	13	.18	.58
2	.47 (.08)	12	.27 (.17)	9	.39	.50
1&2	.42 (.06)	28	.22 (.09)	22	.077	.56

Representational consistency

The pre-test representational consistency did not differ between the intervention and baseline course students (Fig. 3): for the intervention students representational consistency was 76%

and 75% for the baseline students (School1&2). The post-test consistency, in contrast, was higher among the intervention students (83%) than the baseline students (78%), although the difference was statistically almost significant (Mann-Whitney U-test, z=1.71, p=.088).

With regard to the baseline students, there was no significant change in representational consistency (i.e. the difference between pre- and post-test; Fig. 3). With regard to the intervention students, this change was significant (Wilcoxon Signed Rank Test, z=2.80, p=.005). The change was greater in School2 than in School1. In School2, the change of representation consistency was significant for both the intervention (z=2.68, p=.007) and baseline students (z=2.07, p=.038), but it was clearly greater for the intervention students as the effect sizes also indicate (1.25 and .33 respectively). In School1 the change was not significant among intervention or baseline students. The intervention students of School2 exhibited more representational consistency in post-test than the intervention students of School1 (z=2.37, p=.018).

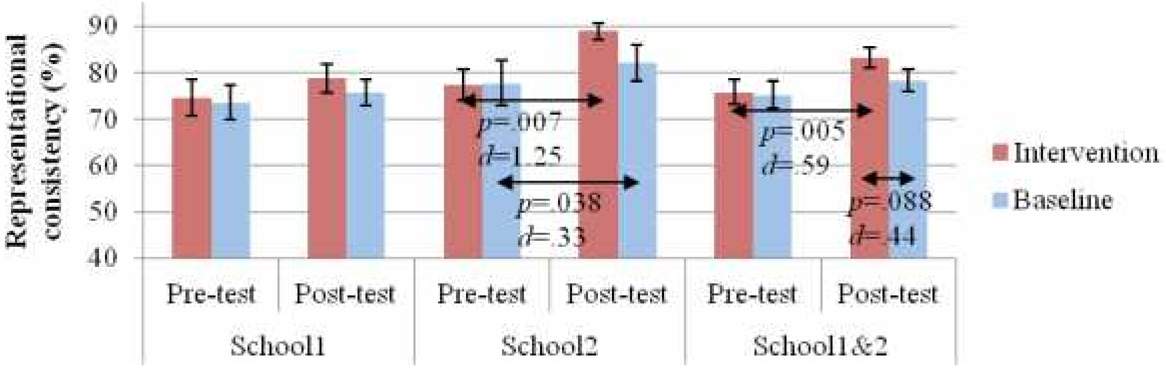

Figure 3. Students' representational consistency in intervention and baseline groups

DISCUSSION AND CONCLUSIONS

The first research question asked how transfer teachers integrated the intervention in their teaching without any extra training. The teachers received no instructions on how to use the intervention material. Both teachers used the material as homework exercises, limiting the teaching time used for the intervention in both schools. The teachers had taught the mechanics course many times before, and they said in the interviews that they had not changed their teaching with the exception of including the new homework exercises (intervention material).

The second research question concerned the effect of intervention on students' conceptual understanding of force and their ability to interpret multiple representations. Despite the lightness of the implementation, the results suggest that the intervention increased students' understanding of force (medium effect sizes for normalized gain of the R-FCI score). In addition, the change of the representational consistency was greater for the intervention students than baseline students, especially in School2. The intervention was used only in the two courses with the small amount of students hence one needs to be careful with the generalization of results to a bigger population. A replication study in other courses and schools would be of value.

The third research question asked what kind of textbook exercises were used from the perspective of multiple representations. We assumed that if the intervention material contained something that the textbook exercises did not include, such as the use of multiple representations and qualitative thinking with regard to forces, this could explain some of the increase of intervention students' learning. Indeed, especially in School1, textbook exercises included few multiple representations and mainly focused on calculation. In School2 exercises contained more representations. Qualitative exercises, which did not demand calculation, were also used more in School2.

Why did the intervention students in School2 seem to benefit more from the intervention than their peers in School1, especially when the textbook exercises of School1 included only a few representations? Maybe School2 students were more accustomed to studying with representations: the students had used the same textbook series in their former physics courses. Or perhaps School2 students benefited from both the intervention material and the multiple representation exercises of the textbook. It should, however, be emphasized that differences between the schools can be caused by many other reasons than just the intervention material. Nevertheless, the material seemed to improve learning in both schools.

The results from this intervention support the assumption that the use of multiple external representations benefits student learning. The ease with which the transfer teachers integrated the material also suggests that this "transfer approach" can be more widely introduced without too much difficultly. Furthermore, the positive results with this light intervention may well suggest that this type of approach could be used more extensively to support student learning.

GENETIC ENGINEERING EDUCATION AND CITIZENSHIP IN TUNISIA

Wided OUESLATI[1], *Laurence SIMONNEAUX* [2] *Atf AZZOUNA* [1]
[1]Institut Supérieur de l'Education et de la Formation Continue, Tunis
[2]ENFA Toulouse

Abstract: This study focuses on a particularly "hot" scientific topic, genetic engineering. This cross- cutting science technology is rolling continuously. It is situated in the crossroads of three big fields of research: the STS, the SSI and the QSSV. Its uncertain implications give rise to heated discussions on the research, media and society level. This is why special attention should be given to ways of putting into practice didactic strategies appropriate to this type of knowledge. Considering the teacher's role in the educational process and the management of the relation knowledge-student, we focus on Tunisian professors' practices in authentic class situations. Through the analysis of the classes and that of the exchanges between teachers and students we try to determine if the subject matter and the way it is taught would allow for the development of the personality and the education of the Tunisian students' as a citizen. However we succeeded to show that the management of the knowledge to be taught by the observed professors doesn't promote this type of education and isn't in adequacy with the nature of this scientific topic.

Keywords: genetic engineering- Tunisian professors' practices- authentic class situations- citizenship

THEORETICAL APPROACH

The teacher has a major role in the teaching/training process. He determines the relationship between the student and knowledge. He organizes the contents of the course and follows the appropriate didactic strategies. This makes his task complex and delicate especially when it deals with a yet unfinished knowledge and social topics such as genetic engineering.

However, in this process, the shifts cannot be excluded, the teacher being a complex person with emotions and representations rooted in his individual and social history. He is present in the didactic situation with his own ideology and his private representations (Joshua & Dupin, 1993).This could have an effect on his way of acting in the classroom, on the processing of the contents to be taught, on his way of interacting with the pupils and thus on their performances. In this regard, the science didactic research showed that the teacher's influence on the pupils' performances is more important than that of the textbooks or teaching strategies (Welch, 1969 quoted by Simonneaux, 2005).

Moreover, the intellectual tools for constructing knowledge are acquired through verbal exchanges. The language plays an important mediating role in the learning process and the teacher occupies a major position in the organization, the management and the dynamics of the interaction in the classroom. In this perspective, several studies have been directed towards the analysis of the dialogue between teacher and student, in the didactic situation.

Rogalski (2006) shows that the piloting of the class is essentially made through the speech of the teacher ; Sarrazy (2001) underlines the role of the didactic interactions of the professor in the process of teaching and the functions which they assure the advancement of the knowledge.; Mortimer and Scott (2003) show that the students' learning process is influenced by the structure of the speech in class ; others provide that the outline and the contents of the interactions allow to report and to differentiate the practices of the teachers (Dunkhin and Biddle, on 1974; Altet and *al* ., 1996, quoted by Clanet, 2005) …

Consequently, we decided to study the didactic practices of Tunisian teachers through their verbal interactions with the students and their contents processing of the knowledge to be taught. We speak of didactic practices as far as they aim directly at the genetic engineering teaching / learning. Our main research question is the following:

> Do the proposed contents, their management by the professors, the structure of the joint action between the professors and the students, and the communicative approach(s) adopted by the teachers, contribute to the education of future citizens?

METHODOLOGY

We observed and audio recorded eight natural science teachers in real situations while teaching genetic engineering in the final year of the high school. The recordings were entirely transcribed.

We opted for a multi-referenced analysis in details, as far as the crossing of the various approaches could enlighten us more on the didactic practices of the teachers and the real curriculum in class. Our analysis contains three levels:

> The macroscopic level: cutting the corpus in steps to follow the dynamics of the teaching process, to reflect different themes as they progress and to develop an overall frame of the lesson.
>
> The mesoscopic level: cutting the steps in didactic games to determine a synopsis for every session of the course. The various

realized "games" are described to compare the contents processing by various teachers.

The microscopic level: it contains three steps:

*First, determining the structure of the joint-action (professors-students) by analyzing the management of the *chrono, meso* and *topo* geneses by the teachers (Sensevy, 2007; Schubauer-Leoni & *al.* 2007).

*Then, characterizing every didactic "game" by using the quadruplet: *definition, regulation, devolution, institution knowledge* (Brousseau, 1986);

*Finally, analyzing the games according to the communicative approach which is particularly centered on the discursive practices of the teacher (Scott and Mortimer, on 2003).

We limit ourselves, in this presentation, to the méso and microscopic levels. We study the contents processing of the knowledge to teach as well as the data obtained from the three analytical approaches quoted above.

We postulate that this type of analysis would favor a complementarity between the various approaches and would allow to report the way according to which the observed teachers manage the development of the teaching/learning process and interact with their pupils.

RESULTS

The results obtained are:

**In the mesoscopic level*

1. The genetic engineering applications are not handled by all the teachers.
2. The ones that are mostly brought up are those with medical purpose. They are perceived only according to their positive aspects.
3. The observed teachers handle neither the social stakes of the genetic engineering knowledge, nor its limits, nor the repercussions of its applications.

**In the microscopic level*

1- Determining the structure of the joint action (teacher-student) shows that the management of chrono, meso and topogeneses is operated by the teacher. He positions himself as a regulator of knowledge. He holds a position based on the development of scientific knowledge and advanced didactic time.

2- Characterizing the games according to the quadruplet of Brousseau (1986) shows that the tasks are rarely defined and never devolved to the students. Besides, the teacher is the one to regulate the knowledge construction.

3- The communicative approach confirms the results obtained from both previous analyses. It reveals certain constants in the management of the knowledge by the teachers:
- Dominance of the exchange patterns from types (Question-Answer) and (Question-Answer-Evaluation) piloted only by the teacher. He is the only one to initiate questions.

- Dominance of an authoritative pseudo interactive or non interactive model, where the teachers position themselves as administrators of the activities. They students are not involved in the knowledge construction. This does not prepare them for citizenship. These teachers focus on the development of the scientific knowledge and even if they are sometimes interacting, these interactions are pseudo interactions to advance the didactic time.

- The dialogical model is almost absent.

CONCLUSIONS

Finally, we can conclude that the contents proposed by the teachers become integrated into a descriptive approach of the genetic engineering techniques, disregarding its multiple applications and social implications of this QSSV.

The dominance of the authoritarian approaches (interactive or not interactive) observed at the teachers end, as well as the carriage they adopt don't involve the student in the teaching / learning process.

We think that discussions held in class about QSSV could increase the interaction between the teacher and the students. This would help moving away from authoritative/non-interactive postures towards a communicative model more emancipated, responding to a dialogical/interactive approach and taking into account the diversity of the students' ideas and their conflicting points of view. Feeling involved in the process of building the knowledge the students will be more motivated to address and discuss issues of broad scientific interest.

Thus we could contribute to the education of capable and informed future-citizens: "to develop a clear opinion regarding these questions, to be able to make choices in terms of prevention, action… and to be able to discuss them." (Simonneaux, 2010, p.)

USING COMMUNICATION PATTERNS FOR ANALYSING CLASSROOM ACTIVITIES IN CHEMISTRY

Tobias Pollender[1] *and Oliver Tepner*[1]

[1]Faculty of Chemistry, Chemistry Education, University of Duisburg-Essen, Germany

Abstract: The presented study is part of the project ProwiN (Professionswissen in den Naturwissenschaften – professional knowledge in science) that explores three dimensions of professional knowledge in science: content knowledge (CK), pedagogical content knowledge (PCK) and pedagogical knowledge (PK) of chemistry teachers. The central aim of this study is to investigate the correlation between PCK and chemistry teachers' classroom activities. For this purpose, a theory-driven category system based on the standards of content analysis is being developed in order to analyse videos of chemistry lessons. This study is predominantly concerned with the analysis of communication patterns between teachers and students. The central aim is to discern how teachers deal with their students' misconceptions. Therefore 25 videos of chemistry lessons available from an earlier video study is analysed with the help of communication process diagrams. Examples of our new developed communication process diagrams as well as results from the first study are presented.

Keywords: pedagogical content knowledge, video category system, classroom activities, students' misconceptions, communication patterns

INTRODUCTION

Both teachers' knowledge and teachers' classroom activities have become focal points in science education research (Baumert, Kunter, Blum, Brunner & Voss et al., 2010; Stigler, Gonzales, Kawanaka, Knoll & Serrano, 1999). One major deficit in chemistry instruction research is seen in the lack of studies that correlate teachers' PCK and teachers' classroom activities (Abell, 2007; Lipowsky, 2006). To that end, advantages of video analysis become obvious. Thus, the main goal of this current study is to develop a video category system in order to evaluate chemistry teachers' PCK while focusing on students' misconceptions.

The main variables that determine successful teaching are (1) the teacher and (2) his or her professional knowledge. Following Shulman's concept of professional knowledge (1987), a theoretical distinction is often drawn between pedagogical knowledge (PK), content knowledge (CK), and the knowledge needed for teaching a specific subject: pedagogical content knowledge (PCK). The presented study is part of the larger project ProwiN that examines these three dimensions of professional knowledge in science, assuming that they influence chemistry instruction and enable us to draw inferences about students' learning outcomes. Although several conceptualisations of PCK have already been developed, there is no generally accepted definition of PCK (Kind, 2009). However, two facets can be seen as key elements of PCK: knowledge of representations and strategies and knowledge of students' misconceptions (Van Dijk & Kattmann, 2010). This study is solely concerned with students'misconceptions/preconceptions.

The interest of scientists in students' ideas and especially in their misconceptions came to prominence at the end of the 1970s and in the early 1980s. Misconceptions mean any concept that differs from the commonly accepted scientific understanding of the concept (Nakhleh, 1992).

The essential purpose of the study is to explore how teachers deal with their students' misconceptions. To do that, communication patterns in the classroom are closely analysed. Pitton (1997) identified typical communication patterns in chemistry lessons: One major pattern is that teachers tend to ask narrow, leading questions and therefore impede qualified statements from their students.

Fundamental to this project are the following research question and hypothesis:

Q1: Is there any difference in terms of communication patterns between chemistry teachers with a high score in the PCK test and those with a low score in the PCK test?

H1: Chemistry teachers with high PCK provide their students more often with the possibility to give reasons for their statements in communication processes than chemistry teachers with a low PCK.

METHODS

For this study, 40 lessons of chemistry teachers will be videotaped. Therefore, a theory-driven category system based on the standards of content analysis is being developed in order to analyse videos of chemistry instruction that focus on students' misconceptions (Bos & Tarnai, 1999). To explore the instructional surface structure (e.g. organisational elements of the lessons) and the deep structure (e.g. teachers' perception of students' misconceptions), low and high inferent categories are designed. Referring to Bos & Tarnai (1999), the development of the coding system can be subdivided in five central steps. On the basis of the theoretical background and research question (step 1), observation categories are identified and category systems are constructed (step 2). These categories are described by an operational definition in a coding manual with rules and indicators referring to both, theory and video data. The categories are repeatedly checked, corrected, and modified. In a further step (step 3) called training session, three coders independently analyse a set of video lessons with the help of the written instruction. There are two ways of realising the video coding process. One method is to watch 10 seconds of the clip, code all variables, and go on with the next 10-second interval (time sampling). In a second type, a clip keeps running until the coder gives an explicit signal to end the coding (event sampling). The coder training in step 3 is completed when the coders reach a direct observer agreement of 60 to 75%. In this study an event based coding is used. Step 4 focuses on the analysis of the data. Finally (step 5), the results are interpreted in reference to the theoretical research questions (Bos & Tarnai, 1999; Janik & Seidel, 2009; Olszewski, 2010; Seidel, Prenzel & Kobarg, 2005). In this study, teachers' PCK is assessed by using a test that has already been developed (Witner & Tepner, 2011).

During the development of the observation tool, a theoretical model (Figure 1) for comprehending the surface and deep structures of instruction is also designed. This model represents concise qualified students' statements:

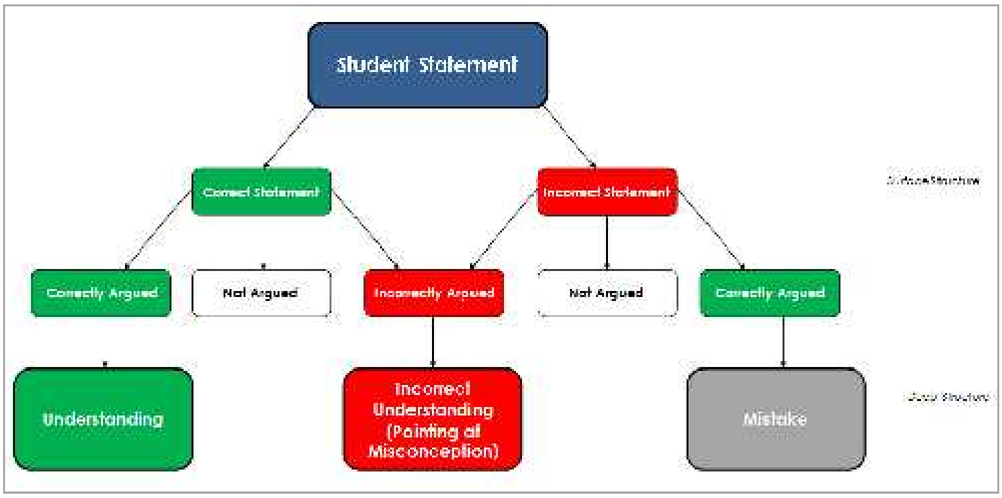

Figure 1. Theoretical Model

To refine this model, video material of 25 chemistry lessons is being analysed with the help of communication process diagrams. The videos belong to two different groups of classes of a grammar school (Gymnasium): One part of the sample (N = 10) consists of 7th grade classes, while the other part (N = 15) consists of 10th grade classes. The video data concentrate on lessons on the topics "state of matter" and "acids, bases, neutralisation". The following diagrams have been designed to evaluate the communication processes in science lessons and, most importantly, to answer how teachers deal with students' statements and misconceptions. Communication patterns in which teachers effectively prompt or ask for reasoned students' statements are important for encouraging students to express their ideas more qualitatively and proactively. Additionally, these patterns are assumed to be a prerequisite for learning about students' misconceptions. The following figure (figure 2) provides observers with a brief overview of a diagrammed lesson:

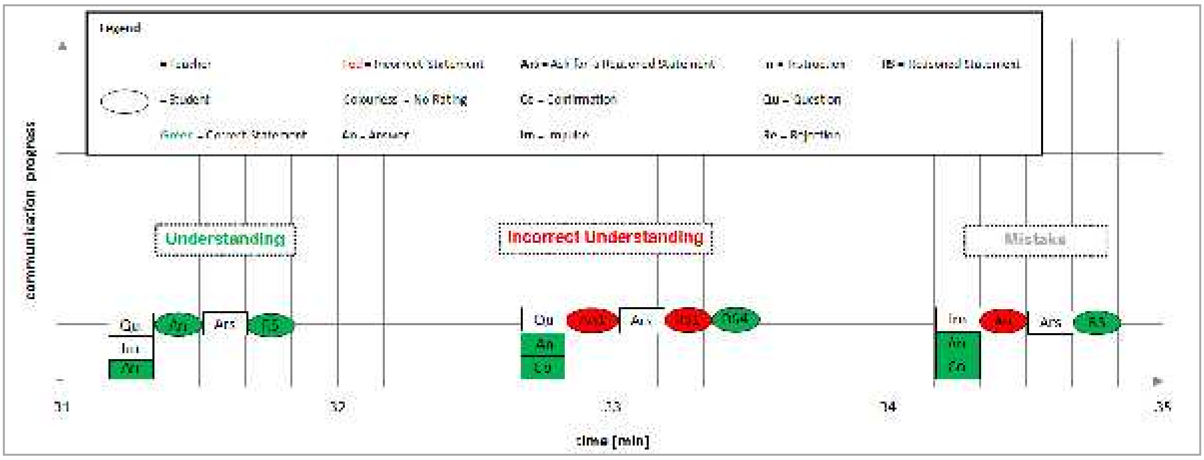

Figure 2. Prototypical Elements of Communication Process Diagrams

The whole communication process diagrams (see Figure 2 for prototypical elements) are developed in a two-dimensional coordinate system with time on the x-axis and communication progress on the y-axis. The prerequisite for using communication process diagrams in the analysis of student-student or teacher-student discussions is a clear definition of the symbols (see shortcuts in the legend). First, there is a distinction between a rectangular symbol for the teacher and the ellipse for the student. The statement of the student or teacher is followed by a specification of the statement: answer (An), ask for reasoned statement (Ars), confirmation (Co), impulse (Im), instruction (In), question (Qu), rejection (Re), and reasoned statement (Rs). The third color-based criterion (green/red) divides between student/teachers' statements which are correct or incorrect from a scientific point of view. With every new scientific statement, the communication progress enters a new level in the diagram. The communication process diagrams show typical communication patterns in a chemistry classroom. In a first step, 25 videos of grammar school chemistry teachers were analysed with the help of communication process diagrams.

RESULTS

The following communication process diagrams represent two examples of communication patterns found in chemistry classes (see Figure 3):

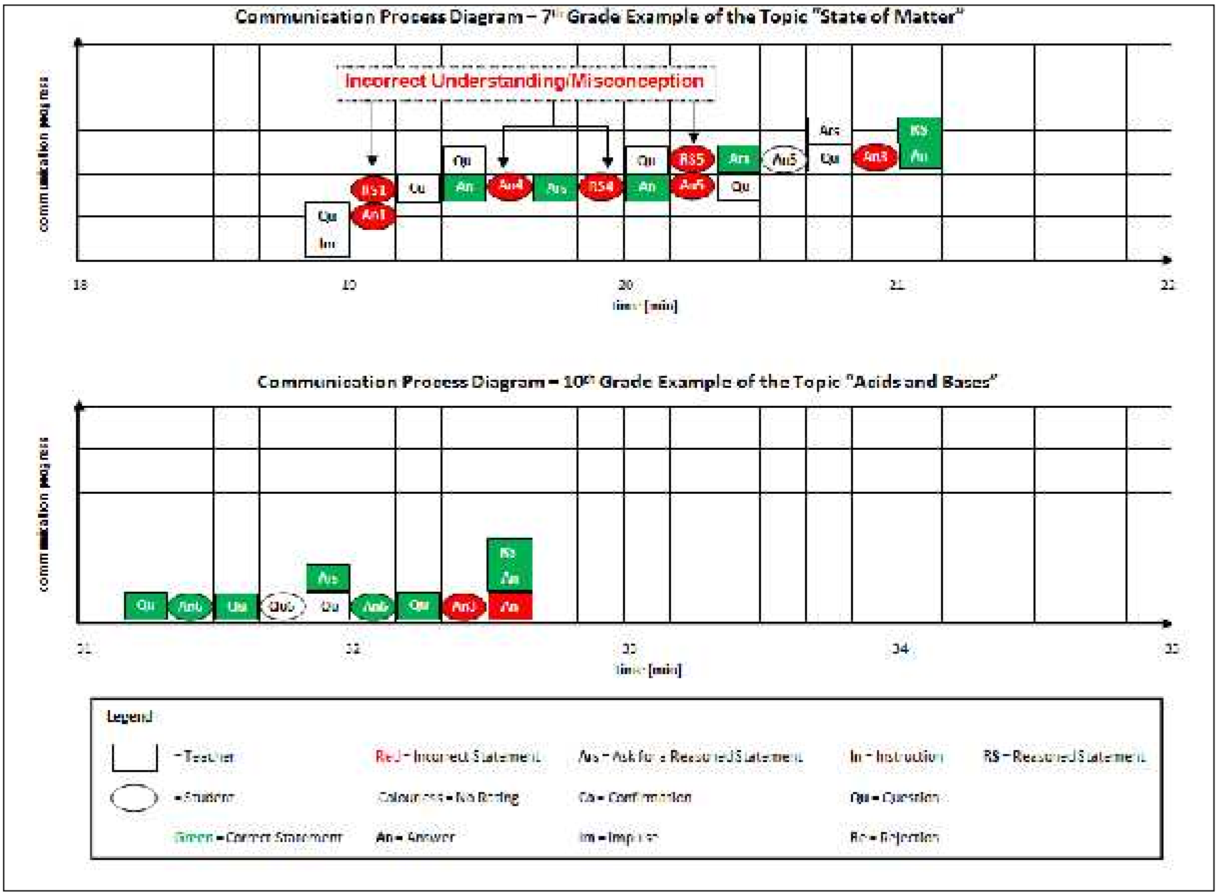

Figure 3. Communication Process Diagram/Example 7th Grade/10th Grade

In order to give a short example for one type of communication process (7th grade) we focus on the communication patterns from minute 18:50 to 20:20. The communication process starts with an impulse and a question of the teacher combined in one statement. Then student no. 1 gives an incorrect answer and a wrong justification. In this moment, the teacher might recognise and act on the incorrect reasoned statement to test if the student has an understanding which is incorrect from a scientific point of view (pointing at a misconception). Instead he continues the lesson with a confirming statement, the correct answer, and the next question. As student no. 4 gives a short incorrect answer, the teacher asks for explanation. The wrong justification follows and the teacher gives the correct answer and poses the next question. Then, a long statement with an answer and explanation, which are wrong from a scientific point of view, is given by student no. 5. This illustrates an incorrect understanding and indicates a new misconception.

The second communication process diagram shows a communication-sequence of two minutes in a 10th grade lesson on the topic “acids and bases”. In minute 31:00 to 32:30, it is shown that the teacher dominates the communication by his way of narrow questioning. The teacher asks a short question which is correct from a scientific point of view. Student no. 6 gives a short correct answer, the question from the teacher follows and the next question from the student no. 6 is articulated. The teacher continues the lesson by giving an impulse and asking a question in one statement. As a consequence, the student gives the next short answer, the teacher poses the next question and the incorrect answer from the student no. 3 follows. There is no opportunity to identify students’ misconceptions as the teacher does not ask them to justify their statements. A student-student or teacher-student discussion is important to learn about students’ ideas. That is a fundamental prerequisite to understanding and dealing with students’ misconceptions.

DISCUSSION AND CONCLUSION

The analysis of communication patterns predominantly shows that the course of the lesson is decisively determined by teachers’ behaviour: Lessons are teacher-oriented and dominated by their activities. Verbal communication, even among students, is also controlled by the teacher. Primarily in 10th grade classes, teachers asked narrow, leading questions by putting the answer in their students’ heads instead of leaving their questions open-ended. The teachers did not seem to take students’ statements seriously. Providing instruction that takes students’ misconceptions into account was barely possible, because extensive student-student and student-teacher discussions were not fostered. Reasoned student statements that would have highlighted any misconceptions were not supported.

In contrast, the teacher in the 7th grade example asked questions fostering students’ reasoning and he seemed to be more competent in identifying students’ misconceptions. One reason for this is that asking for explanation enhances the quality of learning and higher order questions challenge the learners to interpret, analyse, and manipulate information in ways that are not simply routine applications of previously acquired knowledge (Chi et al., 1994; Newmann, 1988).

The presented communication process diagrams can be a helpful observation tool for analysing classroom activities. One strong point of these diagrams is that they clearly illustrate the progression of the lesson and especially how teachers deal with their students’ statements and misconceptions.

ACTING WITH PENDULUM

THE PROCESS MATTERS WHERE THE OBJECT ALSO SHOULD

Oleg Popov[1] *and Thongloon Vilaythong*[2]

[1]Department of Science and Mathematics Education, Umeå University, Sweden

[2]Department of Physics, National University of Laos, Laos

Abstract: This paper analyses factors affecting undergraduate Lao students' activities during their first laboratory work in physics - the pendulum experiment. Seven student groups (of three students each) were selected and video recorded at the National University of Laos. Each recording lasted on average about 55 minutes. In addition, the students' lab reports were analysed. The Cultural- Historical Activity Theory (CHAT) was used as a theoretical framework for the data analyses. The findings indicate that nearly all students had difficulties handling the equipment. Students conducted measurements but did not have clear understanding of the objectives of the experimental task. Their lab reports contained tables with data collected and mathematical calculations but had no discussion related to the physics of the experiment, accuracy of the measurements or reflections about the trustworthiness of the results obtained. The process of doing the experiment appeared to be more important than related learning outcomes. Using CHAT conceptual framework, it is possible to state that the *object* of practical activity was not perceived by the students. They were doing many practical *actions* without interconnecting them into meaningful laboratory *activity*. Lack of experience of doing practical work, gap between theory and practice, poor quality of the lab instructions, and faulty equipment were identified as other factors affecting the efficiency of the experiment.

Keywords: CHAT, pendulum experiment, student activity, undergraduate physics education

BACKGROUND

Practical work is broadly recognised as a necessary component of physics studies at school and university. It intends to help students develop their skills of using experimental equipment, enhance understanding of theories and make them familiar with the routines of scientific work (Lunetta, Hofstein and Clough, 2007).

The Cultural-Historical Activity Theory (CHAT) is used in this study as a theoretical framework to analyse students' pendulum experiments at the National University of Laos (NUOL). The *subject* of this activity is a learner/first year student. According to CHAT (Leont'ev, 1981), any *activity* is directed towards and defined by the *object* of the activity (in our case, laws of physics / phenomenon of periodic movement) and mediated by some *tools* (pendulum, measuring instruments, concepts and formulas). The laboratory activity is taking place in the socio-cultural context of NUOL that does not stimulate the implementation of practical work (Popov, Vilaythong, 2010).

The related learning activity is presented schematically in the fig. 1 below.

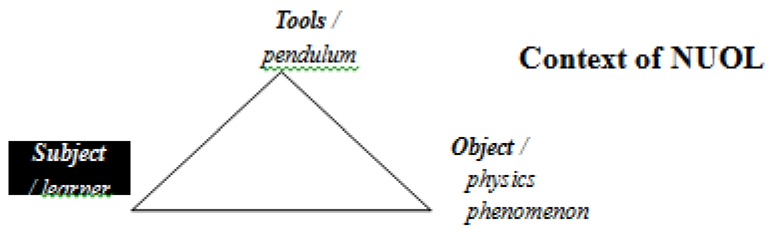

Fig. 1 Schematic representation of learning activity described by CHAT

According to Davydov (1996), any *activity* answers to specific needs of the subject (why to do?). It hierarchically consists of *actions* driven by perceived goals (what to do?) and *operations* that characterise a technical side of carrying out an action, which can be referred to as technique or skill (how to do?). Theoretically speaking, for the success of a learning activity it is important that the students have more-or-less clear answers to the questions posed in the parentheses, i.e. they have to be aware about *object of activity* and capable to carry out intended *actions* with related *operations*. It is then the expected learning outcomes can be achieved.

At NUOL, the introductory physics course for the first year students consists of three components; theory/lectures, problem solving exercises, and experiment sessions. The course is given in the second semester. Students come to experiment class every second week for 1,5 hours. Each class has six different experiment stations, pendulum is one of them. Students do experiments in group but write individual reports following a form given in the lab instruction.

A precarious situation with practical work in physics education in Laos at macro–level (national and institutional) was discussed by the authors earlier (Popov & Vilaythong, 2009). This paper analyses Lao student activities during laboratory work pendulum at micro-level (learner's activity) by focusing on the question: What factors influence student learning from the experiment?

METHODS

The data was collected during laboratory work sessions at the Department of Physics, NUOL in March-April 2008. Seven groups (of three students each) doing the pendulum experiment as the first of six planned laboratory sessions were included in the study. Thus, these students did not have previous experience of doing physics experiments at a university. They took part in an introductory physics course given to the students from the faculties of Forestry, Medicine, Environment, and Science. Many of these students had rather poor knowledge of physics from school and they did not have lectures on the theory of oscillations (pendulum) before the experimental session either.

At the beginning of each laboratory session, the group working on the pendulum experiment was asked permission to be recorded on video. The duration of recording for each group lasted about
55 minutes. Instructions related to laboratory work, video recordings, and student lab reports from the recorded students were analysed.

In the process of videotape analysis the tapes were played at least twice in order to get a clear picture of the students' understanding of the lab instructions, and the factors affecting the students' activities. The lab reports were carefully read with an intended focus of eliciting students' understanding of their tasks and the laboratory procedures reported. The theoretical lens of CHAT was used for interpreting findings.

RESULTS

From the analysis of the lab instruction it became clear that the students were provided information about what they expected to do during the experiment: observe oscillations, identify factors influencing the period of the pendulum, and finding out the value of the acceleration due to gravity, ***g*,** based on the formulas and a graph related to pendulum movement that they had to derive by themselves. Thus, students were given instruction about *what to do*, but not *why* or *how*. They were not informed from the previous theoretical sessions or the teacher / laboratory instructor about the role of the pendulum experiment in their physics course. Why was it important to do the experiment? What principles and laws of physics were they expected to learn from this laboratory work? So, the meaning of doing the pendulum lab activity (its *object*) remained beyond the learning or grasp of the students. The students were merely focusing on the process of conducting different *actions*.

In addition, the process of *how to do*: setting up the equipment, taking measurements and data analysis were not presented clearly enough in the lab instructions either. So, students seemed rather confused in the videotapes when they collected data. They showed difficulty in understanding how to read values of pendulum period on the mechanical stopwatch scale (where one round of the big pointer counts to 30 seconds). They spent a lot of time setting the protractor to measure angles (the equilibrium position of the pendulum was located at 90 degrees on the protractor scale and the angles to be measured as deviations from this position) and resetting the length of the pendulum to exact values as given in the lab instruction. These apparently simple *operations* for university level students that could easily be automatised by now appeared to become rather complex *actions* for the Lao students.

Most of the groups also made a lot of errors during measurements and calculations. The analysis of lab reports showed that the students calculated the value of ***g*** using formulas from the literature and collected data, but the majority got values of ***g*** far from 9,8m/s^2 and did not notice or reflect
in the report about this. Reports contained tables with data and mathematical calculations but no discussions of the physics of the experiment, accuracy of the measurements or reflections about the trustworthiness of the results obtained.

Additional factors affecting the student's activities during pendulum experiment appeared to be related to the quality of *mediating tools* such as lack of students' experimental skills and general knowledge of physics, faulty equipment, and poor quality of the laboratory instructions. These factors mirror the problems in the broader physics education context of Laos where laboratory activities are located (Popov & Vilaythong, 2009).

CONCLUSIONS

The study revealed that the focus of laboratory work was on the processes of manipulating equipment and doing calculations. Students were all the time busy with these two procedures. Apparently the *object* of practical activity was not clearly defined in the lab instruction or by the teachers. Therefore expected learning outcomes of the activity were not clear for the students either. Students conducted measurements but they did not show clear understanding of the objectives of the experimental task and the physics they were expected to learn. The results obtained are in tune with the study of Abrahams and Millar (2008) who found that practical work was effective in getting students to work with equipment but much less effective in getting them to use scientific ideas to guide their actions and reflect upon the data they collect.

CHAT perspective regards the *content* of human activity as determined first of all by its *object* (Leont'ev, 1981). It is therefore possible to state that perceptions of teachers and students of the *object of activity* define how the learning activity is organised and how the learning motives, actions, and strategies of students are shaped. In case of the laboratory activities at NUOL, the *object* of the experiment was not clearly defined and presented by the lab instructions or the teachers. Therefore, students' laboratory activities became rather eclectic collections of different *actions* lacking unifying ideas about gaining adequate knowledge of physics that increased their understanding of certain physical phenomena.

Another factor affecting quality of the pendulum experiment was poor *mediation* of activity characterised by lack of the experimental skills of the students, faulty equipment and lack of some important information in the lab instructions. Theyßen (2007) suggested that for traditional lab work course the theory background for each topic has to be acquired in advance before the experimental phase and all necessary information and advices concerning the experimental tasks should be included in the lab guide. At NUOL students often do the experiments before they get lectures on the corresponding theory, so they do not have necessary theoretical *tools* for grasping the *object* of their learning activity or lab work. Without holistic understanding of the *object of activity*, laboratory work will remain for the students a set of compartmentalised *actions*.

COMMENTS ON THE RESULTS OF A TEACHING INTERVENTION ON EVOLUTION. WHICH PUPILS BENEFITED?

Lucia Prinou, Lia Halkia and Constantine Skordoulis
University of Athens, Greece

Abstract: In the present research the endeavour to teach the theory of evolution by natural selection, which took place in an average state school in Greece, is described. The instruction included efforts to make pupils express their conceptions, to confront them and replace them with more accurate ones. To make this happen the instructional design integrated the pupils' high engagement through discussion and juxtaposition of their conceptions. The purpose of the research was to ascertain a) how were pupils' conceptions formed after the instruction and b) which were the probable reasons that influenced the results of this endeavor.
As the research showed the teaching intervention resulted in more pupils accepting biological evolution and evolution of humankind, the reliability of the theory of evolution and the randomness in the production of the variation. As far as natural selection is concerned, the teaching intervention helped nearly half of the pupils to learn to use it with consistency. Pupils with richer conceptual background were able to see systematically how their prior conceptions contradicted the scientific theory they were taught.

Keywords: Evolution, natural selection, lower secondary school, teaching intervention

BACKGROUND, FRAMEWORK, AND PURPOSE

Natural selection is in the center of the Darwinian theory of evolution. Other procedures have played an important role in the history of life, but no other force except for selection can explain the complexity of life, the intricacy of the survival mechanisms of various organisms and their adaptation to their environment (Futuyma, 1986). Natural selection "is a core concept of the secondary school biology curricula" (Brumby, 1984, p.499) and without a working knowledge of it, it is impossible to understand the diversity and complexity of life (Gregory, 2008).

Nevertheless, a great number of science education research papers (at least in the English bibliography) have shown that many pupils have a plethora of alternative conceptions on the theory of evolution including Lamarckian misconceptions (Enderle et al., 2009; Lucas, 1971; Brumby, 1979, 1984; Bishop & Anderson, 1990; Greene, 1990; Jiménez-Aleixandre, 1996; Samarapungavan & Wiers, 1997; Jensen et al., 2007). A documented presentation of world-wide studies on this issue is presented in Gregory (2008).

A research conducted in a large sample of pupils from many different schools in our country (Prinou et al., 2008) had shown that secondary school pupils appeared to be favorably disposed towards biological evolution. However, despite the fact that the theory of evolution by natural selection was included in the 9th grade biology curriculum, pupils' explanations were teleological (goal-directed). Pupils did not use natural selection to explain evolutionary changes, but treated organisms as a unified total of almost identical individuals, which acquire new traits in order to deal with the needs of the environment. Following that, organisms passed on the new traits to their offspring.

Also, another research conducted in our country (Prinou et al., 2011) indicated that the intuitive teleological reasoning of primary schools pupils (Kelemen, 1999; Bloom & Weisberg, 2007) is not questioned or destabilized during primary education and thus it is

carried on to the next levels of education and it also influences the teaching of biological subjects in higher grades.
According to Sinatra et al. (2008, pp.193-194) learning about a complex process like evolution, requires conceptual change. The educators who foster conceptual change must be aware of students' preconceived ideas that they bring to the classroom, and must design instruction to give them the opportunity to think deeply about alternative perspectives. According to Sinatra et al. (2008, pp.193-194) the likelihood of change relates to the degree of pupils' engagement, that is how deeply students become involved in the content through discussion, debate or dialogue.
Taking into account the result of all the above-mentioned studies we attempted the introduction of the teaching of the theory of evolution by natural selection fostering conceptual change. The instruction took place in an average state school in Greece in the context of the existing 9th grade biology curriculum (as a last unit as it is placed in the curriculum)[1]. The purpose of the research was to ascertain: a) how were pupils' conceptions formed after the instruction and b) which were the probable reasons that influenced the results of this endeavor.

METHODS

- First as *a pre-test* the *Questionnaire1* (Q_1) was given to pupils, that was intended to make pupils express their views and conceptions on this subject. This consisted of open-ended and multiple choice questions. The multiple choice questions were four-grade scale statements (Agree or Disagree absolutely or probably and don't know- no reply). In the open-ended questions pupils were called to explain instances of biological adaptation. The questions excited pupils' interest and this facilitated the conduct of the teaching intervention afterwards.
- The *Teaching intervention*

The subject content: It included basically the following issues: The variety of life and the similarities between living things, the evidence for evolution, Charles Darwin, Natural Selection, The origin of humans.
The *Instructional process that was adopted* (based on the model of conceptual change presented in Sinatra et al., 2008) included the continuous active pupils' involvement in this procedure, which took place with issues and questions that were posed for discussion in the class. The argumentative discussion for (or against) the validity of their explanations on subjects concerning e.g. biological adaptation of a large array of different organisms was used with pupils. Evans et al. (2010) refer that curricula which provide opportunities for generalizing across diverse species are more likely to be successful in relaying evolution.
Very special attention was given to the "language" that was used during the instruction, to make pupils "aware of the conflict" (Sinatra et al., 2008) between the manner concepts (e.g. adaptation, evolution) which are used in everyday language and scientific terminology. The exact content of the concepts and the difference between their meaning in everyday language and the theory of evolution was made totally clear.
The duration of the intervention was eight hours.

- As *a post-test* the Questionnaire 2 (Q_2) was given to pupils. That consisted of open-ended (with other scenarios) and multiple choice questions. The Q_2 was given a month after the Q_1.

The S.P.S.S. statistical program and content analysis were used to process both the questionnaires' replies.
As *a re-test* two optional open-ended questions that were set among others, in the final biology examination (one month later) taken by the pupils, were used. Pupils, who wanted to answer them, did so.

- Regarding the synthesis of the questionnaires and of the teaching material used in the intervention the above-mentioned relevant bibliography on evolution and the site Understanding Evolution[2] were taken into account.

The Participants pupils : 98 pupils of 9th grade, divided in four classes alphabetically. 62.2% were girls and 37.8% were boys. 98 pupils answered Q_1 and 95 pupils answered Q_2. Their general records in biology in a scale 0-20 were: a. the 25.5% had from 17 to 20 (or A), b. the 31.6% had marks from 13 to 16 (or B) and c. The 42.9% of pupils had marks from 9 to 12 (or C).

RESULTS

On the origin of species

The percentage of **76.8%** of pupils who accepted *that the species living today are the result of evolutionary processes that have been occurring for millions of years* when answering the Questionnaire1 (Q_1) increased to **85.3%** when they answered the Questionnaire 2 (Q_2), while the percentages of the other answers decreased.

N=95	Agree %	Disagree %	Don't know- reply %
Q_1	**76.8**	13.7	9.5
Q_2	**85.3**	7.4	7.3

The correlation between pupils' answers in Q_1 and Q_2 on the origin of species proved to be statistically significant with χ^2= 10.733, BE=4 and p-value=0.030<0.05.

On the origin of humankind

The percentage of **59%** of pupils who accepted that *humankind has evolved from earlier forms of life* when answering Q_1, increased to **82.1%** when they answered the Q_2, while the percentages of the other answers decreased.

N=95	Agree %	Disagree %	Don't know- reply %
Q_1	**59**	21	20
Q_2	**82.1**	10.5	7.4

The correlation between pupils' answers in Q_1 and Q_2 on the origin of humankind proved to be statistically significant with χ^2= 22.839, BE=4 and p-value=0.000<0.05.

On the evidence for evolution

The percentage of **35.8%** of pupils *who accepted that the available evidence are sufficient for the theory of evolution to be regarded as reliable* when answering Q_1 increased to **62.1%**, when they answered the Q_2, while the percentages of the other answers decreased.

N=95	Agree %	Disagree %	Don't know- reply %
Q_1	**35.8**	33.7	30.5
Q_2	**62.1**	15.8	22.1

The correlation between pupils' answers in Q_1 and Q_2 on whether the available evidence are sufficient for the theory of evolution to be regarded as reliable proved to be statistically significant with χ^2=19.158, BE=4 and p-value=0.001<0.05.

On the origin of new traits

The percentage of **15.8%** of pupils who accepted *that new traits originate randomly* when answering Q_1 increased to **58.9%** when they answered the Q_2, while the percentages of the other answers decreased.

N=95	Agree %	Disagree %	Don't know- reply %
Q_1	**15.8**	74.8	9.4

Q_2	**58.9**	33.7	7.4

The correlation between pupils' answers in Q_1 and Q_2 on the origin of new traits proved to be statistically significant with $\chi^2 = 12.447$, BE=4 and p-value=0.014<0.05.

On natural selection

Before the intervention the great majority of pupils' answers in the open-ended questions of Q_1 (n=98) did not use scientifically accepted explanations.

E.g. in the question which asked pupils to explain the insects resistance to insecticides[3] the majority of them (75.8%) thought that all organisms (taken as a unified whole of almost identical individuals) "have been transformed", in order to survive or that insects "became accustomed", "acquired immunity, antibodies"etc.

In another question, pupils were asked to explain how a species of wingless insects (feature that helps them not to be carried away by the winds into the sea) came to live on an island subjected continually to strong winds": 65.3% of pupils had answered that "the insects evolved in order to adapt …""their bodies were formed in accordance with the requirements for survival in their environment" or "their wings atrophied because they stopped using them".

The common points between pupils' answers were that the various features were acquired by all organisms (together) in response to environmental pressures. Then their offspring inherited the new traits. Pupils' reasoning was teleological.

After the intervention a number of pupils gave scientifically accepted answers. These answers included the following rudiments:

"In the past … a long time ago…there were some organisms which had the (specific) feature and there were some other organisms which they did not have it. These organisms that had the (specific) feature had an advantage over the others because ….These survived and had children (descendants) which inherited the (specific) feature. These children had an advantage over the others who had not inherited the (specific) feature. The ones who had the (specific) feature survived, while the other died. Gradually …with the passage of time, the percentage of the organisms with the advantageous trait increased… or …now the population consists of organisms with this specific trait…"

Analytically: in the open-ended question of Q_2 (n=95), which was referred to the explanation for the resistance of microorganisms to antibiotics[2], it was found that a percentage of pupils (62.2%) used natural selection.

- In the open-ended question which asked pupils to explain the existence of adaptive traits to dry environments of camels, a percentage of pupils (64.3%) gave a scientifically accepted explanation.
- In the open-ended question which asked pupils to explain another instance of evolutionary change (the cheetahs' ability to run faster than their ancestors[4]) a percentage of pupils (51%) used natural selection.

However, a percentage of pupils continued to answer the questions with misconceptions. The common points between pupils' answers were that the various features of organisms were acquired by all organisms (together) in response to environmental pressures. Then their offspring inherited the new traits. Although pupils' answers had small variations, they described biological adaptation by the use of verbs "organisms mutated, adapted in order to survive, changed little by little from one generation to the next in order to" etc. Their reasoning was still teleological.

N=95	Natural selection	Answers with common misconceptions	No reply/ Tautological
1.Resistance of microbes in	62.2%	29.6%	8.2%

antibiotics			
2.Camels'adaptive traits to drought	64.3%	25.5%	10.2%
3.Cheetahs' ability to run faster	51%	30.6%	18.4%

- The correlations between pupils' answers to each question and their marks in biology proved to be statistically significant. Analytically:

- The correlation of pupils' replies to the first open question and their marks in biology proved to be statistically significant with $\chi2= 32.543$, BE=6 and p-value=0.000<0.05 and showed that the majority of pupils who used natural selection to answer the first open question had high marks in biology i.e. A (the 39.3%) and B (the 32.8%). Also the majority of pupils (the 95.6%) who answered that insects (altogether) "changed" (adapted) in order to survive had average (the 47.8% had B) and low marks (the 47.8% had C) in biology. All the pupils (100%) who answered that they do not know or they gave tautological answers had low marks in biology.
- The correlation of pupils' replies to the second open question and their marks in biology proved to be statistically significant with $\chi2= 18.879$, BE=4 and p-value=0.001<0.05 and showed that the majority of pupils who used natural selection to answer the second open question had high marks in biology i.e. A (the 38.1%) and B (the 31.7%). Also the majority of pupils (96%) who answered that the camels adapted in order to survive had average (the 36% had B) and low marks (the 60% had C) in biology. The majority of pupils (the 80%) who answered that they do not know or they gave tautological answers had low marks in biology.
- The correlation of pupils' replies to the third open question and their marks in biology proved to be statistically significant with $\chi2= 22.610$, BE=4 and p-value=0.000<0.05 and showed that the majority of pupils who used natural selection to answer the third open question had high marks in biology i.e. A (the 42%) and B (the 34%). Also the majority of pupils (90%) who answered that the cheetahs adapted in order to survive had average (the 36.7% had B) and low marks (the 53.3% had C) in biology. The majority of pupils (the 77.8%) who answered that they do not know or they gave tautological answers had low marks in biology.

- The correlations of pupils' replies to the second open question and their conception on the origin of the new traits proved to be statistically significant. Analytically:

The correlation of pupils' replies to the second open question and their conception on the origin of the new traits, proved to be statistically significant with $\chi2=10.826$, BE=2 and p-value=0.004<0.05 and showed that the majority of pupils (70.5%) who used natural selection to answer the second open question accepted that new traits originate randomly.

The correlation of pupils' replies to the third open question and their conception on the origin of the new traits, proved to be statistically significant with $\chi2=6.916$, BE=2 and p-value=0.031<0.05 and showed that the majority of pupils (75%) who used natural selection to answer the third open question accepted that new traits originate randomly.

- **Natural selection as an explanation in all three open-ended questions**

- 43.8% used natural selection in all three open-ended questions.
- Half of these pupils (46.5%) had high grades in biology (A). 80% of them were girls.
- One third of the pupils (30.2) who used natural selection to all questions had μέτριους marks (B). 70% of them were girls.
- The rest of the pupils (23.3%) had low marks. 80% of them were girls.

- **In the re-test** two open questions on (different) instances of biological adaptation, that were given among others in the final biology examinations (one month later) taken by the pupils, were used.

- 92 pupils chose to answer the first open question referring to the evolution of the beaks of birds living on an island with plants producing small seeds. 70.7% of them used natural selection.
- 82 pupils chose to answer the second open question. Pupils were asked to explain the existence of adaptive characteristics of seals. 54.9 % of them used natural selection.
- 53.6 % of pupils who chose to answer both questions (n =82) used natural selection to each one of them.

DISCUSSION AND CONCLUSIONS

The teaching intervention resulted in more pupils accepting biological evolution and evolution of humankind.
The percentage of pupils who accepted the reliability of the theory of evolution was increased. However there were a percentage of pupils which did not answer or accept this statement. A great increase of the percentage of pupils who accepted the randomness in the production of the variation, which is a prerequisite for the "action" of natural selection, was ascertained. Nevertheless there were a remarkable percentage of pupils which had difficulties in accepting the role of chance in the origin of new traits of organisms. As it was shown in pupils' answers and their correlations, the recognition of the role of chance in the origin of variation perhaps leads to the conception of natural selection more easily.
After the intervention, a number of pupils were able to use natural selection in each question, while a smaller percentage used natural selection with consistency, i.e. they used it to answer all open-ended questions.
The great majority of pupils who appeared to be able to use natural selection to answer all questions were pupils with good and average marks in biology, result that could be explained in different ways. A probable explanation is that natural selection is a complex concept and its understanding presupposes the knowledge and understanding of other biological concepts. Probably these pupils had a richer conceptual background that enabled them to see systematically how their prior conceptions contradicted the scientific theory they were taught. The other pupils probably having fragmented conceptual frameworks used natural selection in some questions and they tended to slip into their intuitive teleological conceptions in other questions.
Additionally, a percentage of pupils did not use natural selection but they repeated teleological explanations. Unfortunately these types of explanations had not been doubted during the previous years of pupils' formal or informal education. On the one hand, pupils had been taught the "adaptation of organisms" during the formal education problematically (Prinou et al., 2011). On the other hand, pupils have watched documentaries on television programs etc., where the "adaptation of organisms" is presented problematically also.
Probably there are also other reasons responsible for the fact that pupils were not able to use natural selection. These reasons should be taken into account when designing a new teaching rubric fostering conceptual change for all pupils ; maybe the time devoted to the instruction was limited; or the time when the instruction took place (end of the school year as it was scheduled in the curriculum) ; or perhaps that the intervention did not interest all pupils. M. Evans (2008) has commented that the persistence of misconceptions is probably due to the fact that students who are taught biology are not (always) interested in acquiring a deep understanding to comprehend evolutionary concepts but merely in passing the course.
In the next phase of this research we are going to collect more data through pupils' interviews and recording of their discussions on the previous issues. Also we are going to record the development of pupils' conceptions as they evolve and follow the next school grades.

Abstract: Our research aims at highlighting the conditions that allow the pupils to build up scientific problems during sessions including moments of debate in biology lessons. Our project is in line with the researches conducted in biology didactics on the role of linguistic interactions in scientific learning. In this study, we try to clear up the strategies used by teachers to change pupils' understanding of biological phenomena and encourage their involvement in the building up of a scientific problem. Our research data were collected in a 6th grade class and in a 10th grade class. Through examples observed in these classes, we have examined the way teachers manage a discussion about pupils' different attempts at explanations and how they lead them to change their points of view. In this contribution, two biological topics are concerned: the recycling of theorganic matter in ecosystems (6th grade class); the supply of dioxygen in the body (10th grade class).

Keywords: linguistic interactions, problem building, enunciative posture, professional gesture, inducer of problematization

1. INTRODUCTION

Our research aims at highlighting the conditions that allow the pupils to build up biological problems during sessions including moments of debate in the classroom.

We try to clear up the strategies used by teachers to change pupils' understanding of a biological phenomenon and encourage their involvement in the building up of a scientific problem.

In our analysis of the teacher's activity, we have tested Fabre's and Musquer's hypothesis (2009a, 2009b), especially their idea of "*inducer of problematization*" In spite of the wide variety of inducers of problematization implemented by the teachers, we found similarities between the two analysed sequences. In this paper, we study some of those similarities. This study allows a better understanding of the process of problematization.

2. RATIONALE AND PURPOSE

In French secondary school, science teachers are encouraged (by recommendations from their hierarchy) to organize their teaching around a scientific problem but most often they present the problem to the class and the pupils have to try to solve it. In this case, the question of the construction of the problem is avoided and its role is often underestimated

A specificity of our approach is related to the articulation between the theoretical framework of problem building - elaborated by Fabre and Orange (1997), CREN laboratory, university of Nantes - and a socio-historical approach of learning, which considers that school must allow pupils to rebuild knowledge available in culture and the ways of thinking, speaking and acting associated with this knowledge (LACES laboratory, University of Bordeaux: Ponce & Schneeberger, 2002 ; Lhoste, 2008; Rebière, Schneeberger & Jaubert, 2009; Schneeberger &

Vérin, 2009). More precisely, we assign a decisive role to the pupils' problem building in the construction of biological knowledge.

The teacher's role is complex because he or she must encourage pupils to move from a position rooted in everyday life to a scientific approach. At the same time he or she must ensure a psychological continuity and he or she must also impulse an epistemological rupture between the first questions and the biological problem. Many studies conducted by researchers in biology didactics try to understand how the teacher manages to introduce a scientific problem to the class and to what extent it is possible to associate the pupils in the process of problem building in biology.

With reference to a rationalist approach, we argue that the main goal of science-teaching is to enable pupils to abandon common-sense reasoning and to develop a scientific approach of the understanding of biological phenomena. Such an improvement is possible only if teachers set up adequate teaching situations, which implies obeying specific conditions which characterize the scientific activity. We propose to investigate these conditions, particularly those that promote the pupils' involvement in a scientific problem building.

3. THEORETICAL BACKGROUND

During our research, we used the concept of "inducer of problematisation", developed by Fabre and Musquer (2009a, 2009b). These authors assume that various kinds of "inducers" can act to stimulate specifically different cognitive operations involved in a process of problematization.

Figure 1 is a model of the process of problematisation according to Fabre (2009) completed with inducer of problematisation (Fabre & Musquer, 2009a, 2009b)

Various kinds of "inducers" can act to stimulate specifically different cognitive operations involved in a process of problematisation.

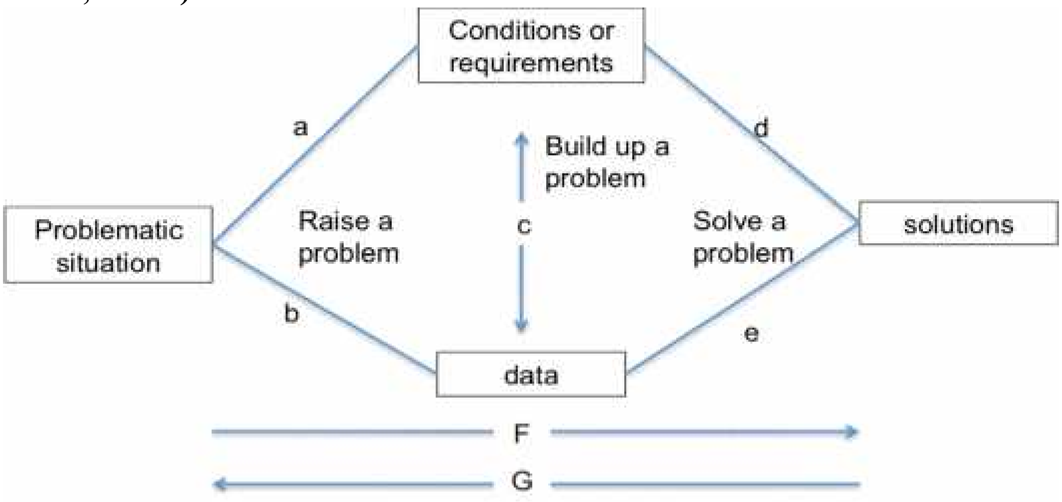
Macroinducers are directly connected to the situations and to the tasks proposed by the teaching devices :

- F: inducer F leads to building potential solutions
- G: inducer G leads to consider solutions, whether possible or not, in a critical way, by reconsidering the problem

Other inducers, less obvious, are linked to the teacher's oral interventions during the debate :

- inducers helping to pose the problem, with more or less specification of the conditions (type a) or the data (type b)
- inducers aiming at the expression of hypotheses or critical analyses of solutions according to the conditions (type d) or the data (type e)
- inducers aiming at connecting the conditions and the data of the problem

Figure 1. Model of « inducer of problematisation » (according to Fabre & Musquer, 2009a, 2009b)



4. DATA & METHODS

Using examples observed in classes of different levels on various biological topics we have examined the way teachers manage debate from different pupils' attempts at explanation and how they lead them to change their points of view (Schneeberger et al., 2007; Schneeberger & Lhoste, 2010). More precisely, we study how the teacher acts in order to make the pupils consider the problem as their own. For this purpose, we examine how the problem, as the teacher formulated it in his or her preparation papers, is introduced to the class, how the discussion before and after its formulation contributes to make pupils understand its meaning as a real problem. We search what conditions the pupils have to build up before understanding the meaning of the question and how the teacher acts to make it effective.

Our research data were collected in a class of 11-12-year-old pupils (6th grade) and in a class of 15-16-year-old pupils (10th grade) whose teachers are associated with the researches conducted by our teams. The data collection took place during sessions including moments of scientific debate in class.

The corpus includes various data
- the teachers' preparatory work;
- the transcripts of the video recordings of the session;
- the transcripts of the teachers' interviews (self-analysis)
- the pupils' written tasks

Two topics were studied during the sessions.
- The 6th grade pupils (11-12 years old) study the recycling of organic matter in ecosystems. This lesson aims at explaining the origin of mineral salts in the soil in order to enable the pupils to connect the presence of mineral matter in the soil with the decomposition of organic matter thanks to the action of the decomposers.
- The 10th grade pupils (15-16 years old) study the supply of dioxygen in the body during physical effort. This lesson entitled "The functioning of the human body" aims at initiating the pupils to the concept of integration of the functions of the human body, as the official French education curriculum specifies: "the contents of this chapter constitute a first approach of the concept of regulation".

4.1. Extracts from the French curriculum

Table 1. The content of the French curriculum

6th grade	10th grade
"Origin of the matter of living beings" (2008) This lesson aims at introducing the pupils to the recycling of the organic matter in ecosystems, so as to take it into account with the objective of sustainable development.	**"The functioning of the human body" (2001)** This lesson aims at introducing the pupils to the ***concept of integration*** of the functions of the human body. The contents of this chapter constitute a first approach of the concept of ***physiological regulation***. *The chosen topic is the study of the variations of the cardiovascular parameters in the human body during physical exertion.*

Our study is a qualitative study. The transcripts of the two sequences were analysed by focusing on what could characterize problem formulation in biology teaching.

Table 2. The two studied classes

6th grade class	10th grade class
11-12 years old, 13 students *10 cm of leaves gather on the soil every year, but after 100 years we don't walk on 10 m of leaves* **Explain what happens to the dead leaves.**	15-16 years old, 30 students *During a physical effort more oxygen is provided to the muscles whereas the oxygen rate in arterial blood remains the same.* **Explain how the muscles are supplied with dioxygen when the consumption increases.**

Our analyses mainly focus on one lesson in each class.

4.2. Methodology

Our methodology includes two steps :

1/ A "microscopic" analysis of every script :

- Identification of moments considered as important with regard to an epistemological point of view.
- Coding of previous interventions with an identification of the different inducers

2/ A comparison between different sequences about different topics observed in classes of different levels

5. RESULTS

5.1. A common characteristic

The analysis of the transcripts of the two sequences has allowed us to identify common points which could characterize problem formulation in biology teaching.

The analysis of the transcripts of the two sequences has allowed us to identify common points which could characterize problem formulation in biology teaching. Indeed, in both cases, the formulation of the paradox (where the problem is) does not appear immediately, contrary to what is implied in the examples of problem situations given by some authors (De Vecchi). Instead, it requires the construction of ideas without which the problem does not make sense for pupils.

6th example

In the sequence of the sixth grade class (recycling of organic matter in ecosystems), in order to formulate the paradox as such (20cm of leaves fall down every year, but after 100 years we don't walk on 20m of leaves), the pupils must have some idea of the conservation of the quantity of matter.

6th grade
After 100 years of deposits of 20 cm of leaves a year, the thickness of the ground has not increased while it should be 20 m thicker.
Condition to raise the problem : the idea of conservation is accepted by the pupils

Before formulating the problem to deal with, and just after having done it the teacher (Corinne) does not prompt pupils to enunciate this condition of the conservation of the quantity of matter straight away, but she leads them to reason in a way that includes this idea. This way, the pupils are enabled to understand the paradox as such (35-36). When the specific problem is formulated, the reasoning the teacher aims at encouraging implies that the idea of conservation is accepted by the pupils.

35	Teacher:	Yes / but once they're on the ground it's no longer living matter / all that can become dead organic matter in the end // the question is what what becomes of that dead organic matter /once it's there (put the « dead MO » label on the poster)
36	Pupil:	It decays
(…)		
42	Teacher:	Yes / we should walk on dead leaves 20m deep
43	Pupil:	Ah //
44	Teacher:	Dead leaves 20m high / that's nearly as high as that building / so when you go for a walk in the forest do you really walk on dead leaves 20m deep ?
45	Pupil:	Well no / xxxx / it's transformed/ xxxx
(…)		
107	Pupil:	Baptiste says it's because of animals / animals make it get smaller
(…)		
113	Pupil:	So Baptiste you said a while ago what animals do
114	Pupil:	They eat them
(…)		

131	Pupil:	But they'll decay anyway xxxx
(…)		
136	Teacher:	What sort of earth does it become //
137	Pupil:	Maybe some sort of a fertilizer
(…)		
150	Teacher:	Stop stop stop / I'll write that/to help plants grow / if your fertilizer helps plants to grow / what does it mean ? / What makes plants grow ? / You know that
151	Pupil:	It 's mineral matter
152	Teacher:	Here we are / Baptiste says it's mineral matter // good, but what are dead leaves ?
(…)		
170	Pupil:	Well / when they decay / they become // they become / as I said before / they become another / another matter / and that mixs with the air
171	Teacher:	Well / Gwénaël says when they decay / they become another matter // all right / so it 's not the same, is it?/ it turns into another / a another matter / because Hugo said a while ago / he said it scatters / Gwénaël says it gets very small // but does it disappear?
172	Pupil:	Well, no

It was only later, when she asked the pupils to look for solutions, that the teacher attempted to make the pupils clarify the idea of the conservation of the quantity of matter (171).

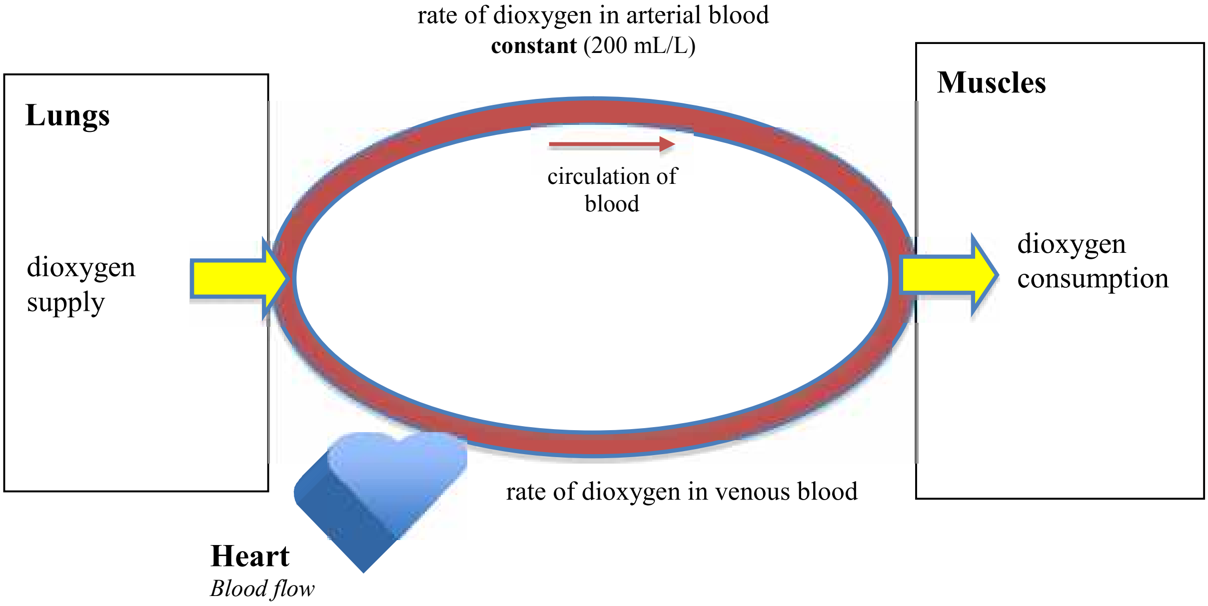
Thus the teacher helps the pupils to think in a way that implies this idea. Then the paradox becomes a paradox for them. Furthermore the teacher's interventions aimed at keywords such as "organic," "mineral," "dead matter" in order to initiate the idea of recycling. What is brought up is not directly the idea of the conservation of quantity of matter, but an idea of “becoming useful”, which anticipates the expected solution. The category “[organic] dead matter”, brought by the teacher led to the notion of a continuum between organic and inorganic matter in the foreshadowing of the cycle she wanted the pupils to build. Paradoxically, we can see that when the pupils tried to formulate the paradox using an example close to everyday life, their oral interventions involved an abstract model of the transfer of matter between plants, animals, soil, using scientific terms (mineral matter, organic matter), a model that they had been taught before. Thus, the notion of discontinuity which is the core of the scientific problem became a central idea in the discussion. The paradox was not formulated with scientific words (dead leaves, etc ...), but with arguments involving quantification, and the pupils attempted to match the two languages (dead leaves, dead organic matter).

10^th^ example

In the case of the other sequence (10th grade), in order to explain the paradox (*more dioxygen is provided to the muscles whereas the dioxygen rate in arterial blood remains the same during a physical effort),* some conditions are also required in order to be able to formulate the problem. The teacher managed to formulate the scientific problem (the paradox defined in section 1) when the pupils seemed to recognize it as such, because different conditions concerning the approaches of the relationships between data (including operating conditions) were identified by them. In the proposed situation, procedural operations are required because the relevant data to take into account in the biological problem studied (dioxygen consumption, dioxygen supply) are not direct data: in order to measure them, one must have the concentrations of dioxygen and use a multiplicative factor: dioxygen consumption = (rate of dioxygen in arterial blood – rate of dioxygen in venous blood) x blood flow.

10th grade
more dioxygen is provided to the muscles whereas the dioxygen rate in arterial blood remains the same during a physical effort
Condition : different conditions concerning the approaches of the relationships between data (dioxygen supply / dioxygen consumption)

Figure 2. The relationships between dioxygen consumption and dioxygen supply in the body



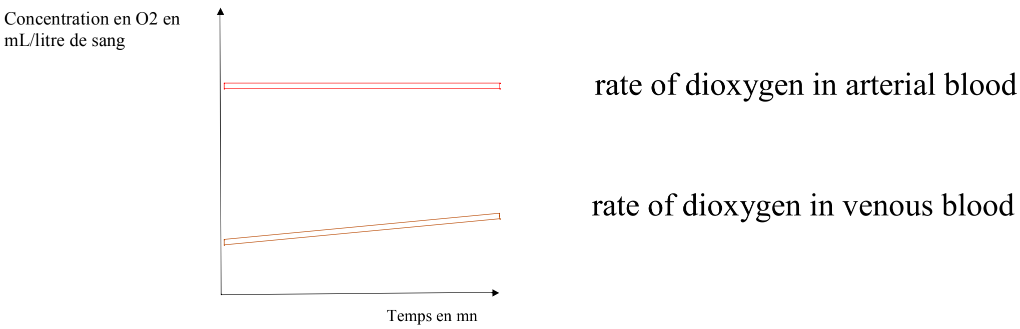
So, learning does not consist in a simple way: from the pupils' experience to more "scientific" formulations. Instead, to make the problem meaningful for pupils, links are required between experiences and models, with the purpose of building a scientific point of view.

5.2. Macro and micro-inducers

In the sixth grade sequence, we could say that, at a macro level, all the teacher's interventions represent a macro-inducer of position of the problem which occurs when she speaks of dead leaves in forests. That is what she wrote in her preparation paper, before the lesson. But before doing so, in each intervention (micro-inducers), she tried to make sure that the pupils build up the conditions so that the problem became a problem for them.

In the tenth grade sequence, the pupils must consider two curves at the same time (showing them the difference between the rate of dioxygen in arterial blood and the rate of dioxygen in venous blood) but they do not do it spontaneously. Usually, they first focused on a single curve. The micro inducers of the teacher this time aims at leading the pupils to take into account the two curves, and at focusing on their distance.

Figure 3. Production of one the group of students



Pupil:	I don't understand how there can be more dioxygen at the end than at the beginning
Teacher:	What matters is not each separate curve, but both considered at the same time / together it's the gap(s) / difference(s) between them/ The same blood ran through the muscles

So there seems to be a link between macro-inducers of the formulation of the problem with micro-inducers involved in the building up of the conditions which make this formulation possible. These conditions may also be conditions of solutions of the problem.

In both cases, the formulation of the paradox is possible thanks to an articulation between macroinducers and microinducers :

- Macroinducteurs G (in connection with the general organization of the sequence) in this case a criticism of pupils' answers

- Microinducers (a, b) (in connection with linguistic interactions).

6. CONCLUSION AND IMPLICATIONS

In this study, the methodology based on the comparison between two sequences using the model of inducers of problem building leads us to find similarities and differences.

The formulation of the problem is possible only if some necessary conditions have been constructed beforehand. So, not only the problem's solution has to be built, but also its formulation. Our "microscopic" analysis shows an articulation between these conditions and the identification of data to allow the pupils to build up the problem (theoretical data in the 6th grade, empirical data in the 10th grade).

We bring to light some differences.

In the 6th grade, the pupils' phrasing is not in accordance with scientific discursive community: they use scientific terms and everyday terms without making any difference between them.

In the 10th grade: pupils' phrasing is in accordance with scientific discursive community, but they have to improve their conceptual apprehension of experimental data.

Experienced teachers know that and do not start with giving the problem to be solved straight away, but first use macro-inducer of problem formulation articulated with micro-inducers so as to make the problem appropriatable by pupils. When training teachers, it could be useful to explain these articulations.

Our research has implication in two different fields:

Concerning research field, our results lead to a criticism of theorical models of problem building and inducers of problematisation.

Concerning teachers' training, our results lead to identify didactical skills teachers must develop in order to help pupils to build up scientific problems.

Acknowledgements

GREEK TEACHERS' ATTITUDES, BELIEFS, KNOWLEDGE AND CONTEXT, CONCERNING EVOLUTION TEACHING

Panagiotis Stasinakis[1] *and Kyriacos Athanasiou*[1]
[1] University of Athens, stasinakis@biologia.gr, kathanas@ecd.uoa.gr

Abstract: The aim of the present study is to record and assess several issues regarding teaching evolution in the Greek school since relatively little is known about the ways in which Greek secondary teachers understand the science of evolution and how they plan to approach most of the issues related to the teaching of evolution. In this study we performed ten one-on-one interviews, of approximately one-hour duration each. Interviewed teachers of several academic backgrounds were all teaching biology in secondary education. The recordings of the interviews were analyzed with the Qualitative Content Analysis (QCA) method and for the data mining the NVivo 8.0 software was used. Our findings indicate a shortage of proper teaching skills in the teaching of evolution among Greek-biology teachers, due to a lack in both, an acquaintance with general teaching strategies, in one hand, and a familiarity with the particular concepts related to evolution that they must transmit to their students. This is combined with the fact that some of them communicate the very same alternative ideas on evolution that one anticipates only from students to have. Finally, others encounter uneasiness to teach the particular subject due to their religious beliefs, a situation that is reflected on the effectiveness of their teaching, even when they try not to communicate this controversy to their students.

Keywords: evolution, biology, qualitative, greece, secondary- education, nvivo.

BACKGROUND & PURPOSE OF THE STUDY

Various scientific and other institutions consider evolution to be the central, unifying theme in biology and many science and science education associations have released position statements expressing their support for the teaching of evolution in science classrooms (Dobzhansky, 1973; National Academy of Sciences (NAS), 1998; National Association of Biology Teachers (NABT), 2002). Nevertheless, large percentages of science teachers reject evolutionary theory and support the teaching of antievolutionary ideas in schools (Nehm & Schonfeld, 2007). Thus, despite overwhelming agreement from the scientific and science education communities, evolution remains a problematic subject for many science teachers.

Numerous studies have explored contextual factors that complicate the effective teaching of evolution in schools. Teachers often do not want to teach evolution (Aguillard, 1999), do not feel adequately prepared to teach it (Aguillard, 1999; Griffith & Brem, 2004), and do not understand the legal precedents associated with evolution education (Moore, 2004). Many communities, school boards, and parents challenge teachers when they follow state and national standards and teach evolution (Chuang, 2003). These and other contextual factors are not surprisingly associated with teachers' emotional stress and negative perceptions regarding evolution (Brem, Ranney, & Schindel, 2003; Griffith & Brem, 2004). The teaching of evolution is a significant challenge for many science teachers. Finally, science teachers have conceptions about learning and teaching sciences, as a result of the many years they themselves have spent in school and university, accepting or rejecting the roles of their own science teachers (Hewson & Hewson, 1989).

The aim of the present study is to record and assess several issues regarding teaching evolution in the Greek school. More specifically, during the application of semi-structured interviews, we addressed the following research questions:

1. Which are the attitudes and beliefs of Greek teachers in regard to evolution teaching and how these affect their teaching practice?
2. How does the scientific and educational knowledge they have acquired during their studies or their professional development activities facilitate their teaching practice?
3. Do they find any particularities in the Greek school context that raise difficulties if they choose to teach evolution?
4. Is their religiousness engaged in any way to their teaching practice?

The open-ended structure of the interviews allowed the freedom of expression, which was anticipated to effectively capture answers in our research questions.

STATUS IN GREECE ABOUT EVOLUTION TEACHING

In the period we performed these interviews (spring of 2009), in the Greek educational system of secondary education (Gymnasium and Lyceum) there are three classes in each grade. But we teach Biology only in two classes, A and C for Gymnasium and B and C for Lyceum. C Gymnasium is the last class of compulsory education, and B plus C of Lyceum are two classes that basically prepare students for National Exams in order to enter the University. A chapter for Evolution is taught only in C Gymnasium, and the period we conducted the interviews there was not chapter about evolution in Lyceum.

Only the next school period, 2009-2010, a chapter for Evolution is part of the teaching material in C Lyceum, for all students, and was compulsory for the national exams (the situation is the same so far). Moreover, all science teachers (biologists, physicists, chemists, geologists, naturalists) can teach Biology in any grade (Gymnasium or Lyceum) in any class, although the headmasters always try to have a Biology teacher in their school at least for Biology in C class of Lyceum.

RATIONALE

While there is a growing body of literature about teachers’ attitudes and understanding of biological evolution in various international settings, relatively little is known about the ways in which Greek secondary teachers understand the science of evolution and how they plan to approach issues related to the teaching of evolution. Moreover, so far there are no data about educational context in Greece that might influence evolution teaching. Based on these results we focused on Pedagogical Content Knowledge (PCK), which will be examined in a further study. In this study, we focused especially on teachers because their role in evolution teaching is less studied, while there is only a minor report concerning teachers (Prinou, Halkia, & Skordoulis, 2005) and some other data concerning students (Kampourakis & Zogza, 2009).

METHODS

The research project is consisted of ten one-on-one interviews, of approximately one-hour duration each. Interviewing seems to be the most suitable method for this study because during discussion interviewers talk about several issues which cannot be pre-defined, as in a questionnaire. All interviews were semi-structured, having additional benefits: interview needs to leave room for the interviewer to ask clarifying questions. For credibility issues we made a member-checking analysis and also used a triangulation analysis in different levels, such as analysis from different researchers, using different analysis methods.

Interviewed teachers were from several scientific academic backgrounds: six biologists, two physicists, one geologist and one naturalist. All of them were teaching biology in secondary education, either in Gymnasium (13 to 15 years old students) or/and Lyceum (16 to 18 years old students). Their teaching experience ranged from 4 to 30 years.

All ten interviews were conducted and recorded. We ensured that the interviewees felt comfortable and were willing to discuss several issues. The recordings of the interviews were analyzed with the Qualitative Content Analysis (QCA) method (Mayring, 2000). For better analyzing and data mining the NVivo 8.0 software was used. We had to be familiar with NVivo8.0, so first we tried to learn the basic functions of this software and then to apply our analysis methods. Parallel to the use of NVivo8.0 we applied other analysis methods, as well, in order to ensure the accuracy of our results.

The data analysis procedure consisted of four steps: a) interviews were transcribed and analyzed, b) passages of the interview text related to the main research questions were chosen from the recording of the interview, c) different text passages concerning the same issue were categorized and integrated, d) categories within the different interviews that concern similar issues were brought together in order to get a picture of the main categories within this study.

During the analysis we reported codes (these are called “nodes” in NVivo), i.e. categories or subcategories for specific issues. For any of these codes we made several references which referred to words, phrases or even paragraphs with content relative to the specific code.

RESULTS

In brief, analyzing interviews and mining data from NVivo software, gave the following results:

- All ten interviewed biology-teachers think evolution as a central, unifying theme in biology and try more or less to teach it. They report evolution teaching as a problematic subject because of its reasoning and impact in several aspects of life. Even biology-major teachers, during their university studies learned about evolution at a high academic level, inappropriate for transforming scientific knowledge to school. It sounds peculiar, but some of biology-major teachers did not have any evolution course during their academic studies.
- Teachers report evolution teaching as a problematic subject because of its reasoning and impact in several aspects of life. Even biology-major teachers, during their university studies learned about evolution in a high academic level, inappropriate for transforming scientific knowledge to school knowledge. It sounds peculiar, but some of biology-major teachers did not have any evolution course during their academic studies.
- Teachers notice the importance of teaching evolution in primary schools and all of them understand the importance of evolution teaching. They feel inadequate to teach evolution and ask for more training on this specific subject or on how to teach the whole biology course. On the other hand, we can see that all of them focused on obvious misconceptions and did not take into account other more important parameters, such as teleological explanations, they do not really understand what evolution as “the unifying theory of biology” means and preferred to discuss evolution only within the context of the specific chapter. In some instances they were confusing the word “unifying” with the word “unified”.

Teacher:…well…ah…I think that according to up to now data we have, I think it is (the TE), a unified theory…I don't know what in the future will emerge…

- Some of the Biology teachers showed a total ignorance of the Nature of Science (NOS) in connection to the teaching of Evolution. At least one confused the term "theory" with an "idea".

  Teacher: …Telling your students about the theory of evolution is similar as telling them you choose…if you wish to call it a theory or an idea…it's up to you...

  This is probably related to the fact that during their studies they followed a curriculum totally directed towards Science in the typical context, without any enrichment with Epistemology, History and Didactics of Science. The historical view is absent in most of the interviewers' classes.
- Most teachers usually do not teach evolution, because of various weaknesses of the educational system: for example, evolution is the last unit in all textbooks, students' specialization in classes of Lyceum, there is ineffective cooperation between teachers and their mentors and lack of teacher training on this specific topic especially for non-biology majors, there is no any biology course in one out of three grades in Gymnasium and Lyceum, etc.
- They report lack of scientific and didactic knowledge in order to teach this specific topic of biology. This concerns both biologists and non-biologists teachers of biology. Moreover, most of the interviewers have no academic background about pedagogy and we reported some common misconceptions:

Teacher: ...natural selection involves organisms 'trying' to adapt", "natural selection gives organisms what they 'need...

All these result to inadequacy, decline self-confidence, stress, and trigger-off difficulties in teaching evolution.

- While all of the teachers in our study accept evolution to be either "a true theory" or a fact, most of them declared to be religious to various grades and shades. Some of them experience a controversy between their religious beliefs and their scientific understandings but they try not to communicate this controversy to their students. The type of the religiosity they have, does not discourage them from teaching evolution. While influences them in their personal thinking, at the same time helps them to address the subject in a different way from the one encountered in similar studies, let's say in USA, where students and teachers are taking Genesis in a literal way, even after evolution teaching (Nehm & Schonfeld, 2007). Nowhere in our study we encountered with teachers trying to persuade students for creation; basically we concluded that they would prefer not to talk about this issue (God, religion) in their classes, because they consider it as personal beliefs. For this reason they report that sometimes they feel embarrassed when they have to conflict with students' religiosity, but they really do teach science and report that none exogenous agent keeps them from teaching evolution.

Teacher: ... I try not to be wrong from the point of view of both theologians and biologists… that is to say. I do not give an answer that would be an error from the one or the other side…

Teacher: ... on the contrary I believe that we do not include by no means perfection because if existed perfection… they wouldn't exist [such monsters] that are created… if they were all so much perfect why so many types of species during the years were disappeared? … I believe that this is what the religion says. Something like that. I believe, I do not know… that all have come into existence in order to glorify the God…

Teacher: From a side I do not want to offend the religious believes the children have…that is to say… as an example… it had been said by some person that I suffer that I do not believe because at least those who they believe they believe that exists something else after the life…

Interviewer: As for Adam and Eve?
Teacher: That, I would answer, is part of the Hebrew mythology and they do not concern us today.

- They don't use the curriculum for their teaching, just the textbook. So their teaching is limited to the issues described in the textbooks and do not rely on targets, misunderstandings, teaching strategies, basic ideas and prerequisites which are defined in the Curriculum. So we noted differences in teaching progress, because the teachers have no common bases about what, how, and why they have to teach Biology and especially evolution. This problem becomes huge, if one takes into account that during their university studies, non-biologists did not take any biology course. Even biologists who had at least one course about evolution, they had it presented from a researchers' point of view and level with the result of being useless for their capacities as teachers of evolution in a school class. And if the absence of scientific knowledge about evolution seems as puzzle, the biggest problem is that no one of our interviewees had any course on the Didactics of Biology or any other course on Science Teaching. Only the neophytes of them during the first year of their teaching in school took part in a professional development course that included general teaching principles, but not Biology didactics, far more, any evolution teaching.
- It is important to mention that in one case when the teacher tried to reform the relationship between her students and the natural world using outdoor activities, including a museum visit, or giving the students the opportunity to see and touch fossils, the results were positive and students were more prone to evolution teaching, from there on. We think that it wasn't by chance that this specific teacher was a naturalist.
- Teachers of Biology in our study do not describe any social pressure against evolution teaching nor in schools neither in social settings.

CONCLUSIONS AND IMPLICATIONS

To sum up, our findings indicate a shortage of proper teaching skills in the teaching of evolution among Greek-biology teachers, due to a lack in both, an acquaintance with general teaching strategies, in one hand, and a familiarity with the particular concepts related to evolution that they must transmit to their students. This is combined with the fact that some of them communicate the very same alternative ideas on evolution that one anticipates only from students to have.

Others encounter uneasiness to teach the particular subject due to their religious beliefs, a situation that is reflected on the effectiveness of their teaching, even when they try not to communicate this controversy to their students. All these barriers underline the necessity to enhance the teaching of evolution theory in Greek Biology departments in a less "scholarly" way and improve in- service and future- teachers' training in pedagogical content knowledge in general and as concerning evolution teaching. Moreover, it is a necessity that there must exist training programs for teachers about evolution, so to make clear that evolution teaching is a unifying idea and can be taught throughout all biology units.

We see there are no exogenous factors that influence the way teachers teach evolution, or any complications due to religion beliefs. As far as religion is concerned, we conclude that this is an issue only for spiritual status of teachers, and does not affect the way they teach in general or evolution especially. The case seems to be different from cases like the one found by Nehm & Schonfeld (2007) for USA where they found that the increases in teacher knowledge about evolution and the nature of science did not translate into greater preference for teaching evolution in schools or greater acceptance of evolution, as it was depicted in their attitudes toward creationism. The latter, has been discussed by us in some other work and has being explained within the context of conceptual ecology that characterizes people from different social and religious backgrounds, affecting their attitudes towards evolution teaching and acceptance (Athanasiou & Papadopoulou, 2011).

We find several difficulties of school reality (such as apathy of the students, or missing hours for teaching, or inappropriate teaching material), but we are convinced that if teachers plan their lessons according to the curriculum and choose teaching strategies adapted to their classes, all these could be overwhelmed. All teachers have a positive attitude about evolution teaching, and this is an important base in training them adequately for evolution teaching.

Teachers should act as everyday researchers in their classroom, not only to teach but also to assess their teaching strategies, to take into account the class context, to evaluate their work and to cooperate with other colleagues in order to achieve the best result for their students. In this effort they need help from the state. The most appropriate and direct supporter, is the School Consultant and all of them, teachers, consultants, ministry officials of education should redefine the value and the role of consultants. We believe that they could offer a great job, because they are the intermediate between teaching practice of teachers and the state's strategy.

Finally, we should take into account not only the misconceptions about evolution teaching, but moreover the prerequisites that students should acquire in order to achieve long-term understanding of evolution teaching.

Our study project is continuing, in two directions: we focus on the PCK and investigate teachers PCK about evolution using questionnaires and organize a training program about evolution teaching using the Moodle e-learning platform. .

DESIGNING VIRTUAL EXPERIMENTS IN ELECTRIC CIRCUITS BY HIGH SCHOOL STUDENTS

Athanasios Taramopoulos[1], Euripides Hatzikraniotis[2] and Dimitrios Psillos[1]

[1]Department of Primary Education, Aristotle University of Thessaloniki, Thessaloniki, Greece

[2] Department of Physics, Aristotle University of Thessaloniki, Thessaloniki, Greece

Abstract: The purpose of this study is to evaluate the effect of investigative activities in virtual laboratory environments to the ability of students to design and perform experiments in the field of electric circuits. An inquiry-based teaching intervention with a degree of guidance from cookbook lab to challenge lab was applied to 14-15 years old high school students. A post-instructional assessment scheme with two extra tasks was used to evaluate the students' experiment design and execution skills. The students' skills were rated in ten dimensions and scored according to a 3-level ranking scheme. Results show that after instruction most students demonstrate a moderate ability in designing and performing simple experiments in the field of electric circuits.

Keywords: experiment design, electric circuits, virtual laboratory

BACKGROUND, FRAMEWORK, AND PURPOSE

Recent studies suggest that virtual laboratories (VL) provide affordances which can support students' engagement in experimental investigative activities and enhance their understanding of aspects of scientific inquiry (Klahr et.al 2007). Well designed guided-inquiry activities utilizing a virtual laboratory can involve students in scientific knowledge quest and may thus enhance their ability to design and perform scientific experiments. However, research has focused mainly on the effectiveness of VL to conceptual enhancement (Zacharia & Olympiou 2011); the potential of VL to foster the development of students' experimental design skills has not been adequately studied. Only recently have such studies been conducted in mechanics (Klahr et al. 2007) and thermal physics (Lefkos et al. 2011).

Our aim here is to extend this research to the field of electric circuits by studying whether the engagement of 14-15 year old high school students in a virtual laboratory (VL) environment carrying out a sequence of investigative activities can result in the development of their ability to design experiments in order to solve simple problems concerning electrical circuits.

RATIONALE

The ability to design experiments is considered to be one of the most important of the skills linked to laboratory investigations possibly surpassing in importance even the actual execution of the experiment as it is related not only to the content under study but to scientific methodology as well (Johnstone & Al-Shuaili 2001, Garratt & Tomlinson 2001). Virtual laboratory environments provide a powerful tool for investigative activities, since students can design aspects of an experiment using multimedia facilities, easily manipulate objects and try out investigations. Our approach draws on teaching science as inquiry utilizing an open virtual laboratory environment involving students in guided experimental activities. In designing experiments students are involved in identifying variables, listing the devices and instruments needed, describing the experimental setup, the phenomena taking place and the experimental process, taking and analyzing measurements, and evaluating results. Guidance is gradually fading away during the course of the activities and students are prompted to design the investigating experiments on their own.

METHOD

The teaching intervention took place in a junior high school in Greece in the field of electric circuits as part of the compulsory physics course. The sample consisted of 16 students of the 3rd grade of junior high school (Gymnasium), 14-15 years old. Instruction involved five units and made use of the 3-dimensional virtual reality electric circuit laboratory of the Open Learning and Laboratory Environment (OLLE). OLLE, as shown in figure 1, is an open learning environment that supports doing science by open experimentation and investigation (Psillos et al. 2008). Students had previously some familiarization in performing hands on and virtual experiments in introductory electricity but they had no involvement in designing experiments.

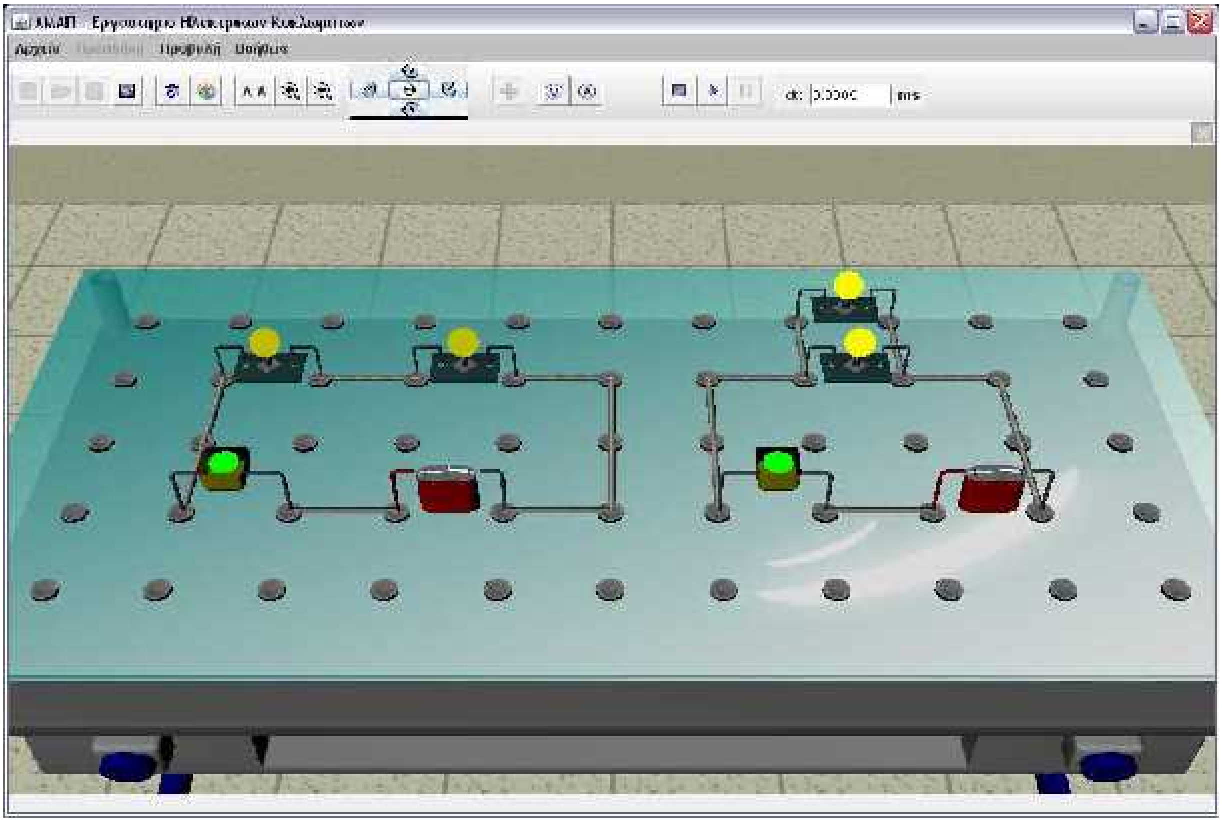

Figure 1. *The electric circuit laboratory of the Open Learning and Laboratory Environment*

According to the classification reported by Du et al. (2005) the guidance of the activities varied from cookbook lab (complete guidance) to challenge lab (guided inquiry). In the first unit (Ohm's law) students follow the directions of the worksheet and using the virtual laboratory equipment construct the given circuit and collect data (cookbook lab). In the second and third units (Kirchhoff's two laws) students followed instructions and using the virtual laboratory equipment construct the suggested circuit, collect and analyze data in order to (re) explore Kirchhoff's first and second law (structured lab). In the last two units (total resistance of resistors connected in series and in parallel) the students had to design the appropriate circuit and follow their own experimental procedure to take measurements and collect and analyze their data (challenge lab).

A post-test only design was applied since students had no experience in the design of experiments prior to instruction. It involved two assessment tasks of measuring the unknown resistance of two electric devices of OLLE at the end of the instruction (one with small resistance and another with large resistance). Students were asked to hypothesize on the outcome of their measurement, identify the variables affecting their measurement, list the devices needed for the experiment, design the appropriate circuit, describe the phenomena taking place and the experimental procedure, construct the circuit, take and analyze measurements, and evaluate their results. After the first task there was a short discussion on students' answers on the task in order to facilitate their thinking on their designs. An excerpt of the worksheet of the second assessment task is shown in figure 2.

Prediction

Do you think that a voltmeter resists the flow of electric current?

....

If so, is its internal resistance large or small? Why?

....

....

....

....

Prediction verification

In order to answer the above questions you will need to experimentally find the internal resistance of a voltmeter. When the voltmeter is connected to a circuit, which quantities do you need to know in order to estimate its internal resistance?

....

....

Which instruments would you use to construct an appropriate circuit for measuring and estimating a voltmeter's resistance?

....

....

....

....

....

Draw the schematics of a circuit with which you can realize the appropriate measurements.

What do you expect to happen when you turn on the above circuit?

....

....

....

....

....

Figure 2. *An excerpt of the worksheet of the second assessment task.*

The students' ability to design and perform experiments was evaluated by using a rubric of ten dimensions, (Anagnos et al. 2007, Lefkos et al. 2011). More specifically, the students were asked to hypothesize on the outcome of their quest (hypothesis forming), identify the variables which are relevant to the phenomenon under study (variable identification), list the devices that need to be used in order to answer their experimental question (devices and instruments), draw the schematics of the circuit to be constructed (device setup), describe what happens when their circuit operates (phenomena description), describe the data taking process (process description), construct the circuit in the virtual laboratory environment (object handling), make the necessary measurements (data acquisition), analyze their measurements (data handling), and record and evaluate their results (results recording and evaluation).

Students' answers were evaluated according to a 3-level scoring scale, similar to Lefkos et al. (2011). If an answer is missing or is incorrect the student gets 1 score point for that answer, if it is partially correct but incomplete the student gets 2 score points and if it is correct and complete the student gets 3 score points.

RESULTS

The results for the two evaluation tasks are shown in Figure 3. It is evident that most of the students are capable of performing correctly at least partially most of the parts of the two tasks (levels 2 and 3). In the second task students performed slightly better than in the first one though the difference was not statistically significant. This may be attributed to the discussion of the students' answers on the first task which took place before the second assessment task. The students reflected upon their mistakes and were able to produce higher level answers in the second task.

The best scores (highest percentage of students completing correctly a specific task) appear in the skill of object handling, where students had to construct their circuits, indicating a high familiarization level with the virtual equipment. This is to be expected since, as stated above, students were familiar with OLLE objects in introductory electricity prior to the instruction reported here. The worst scores (lowest percentage of students completing at least partially a part of the assignment) appear in the skill of hypothesis forming, especially in the second assessment task (large R measurement). This possibly occurs because after the discussion of their responses to the first task (small R measurement), students adapted their answers to that task and failed to make correct predictions for the second task (large R measurement). However, this mistake did not prevent them from carrying out the rest of the task and correcting their initial prediction

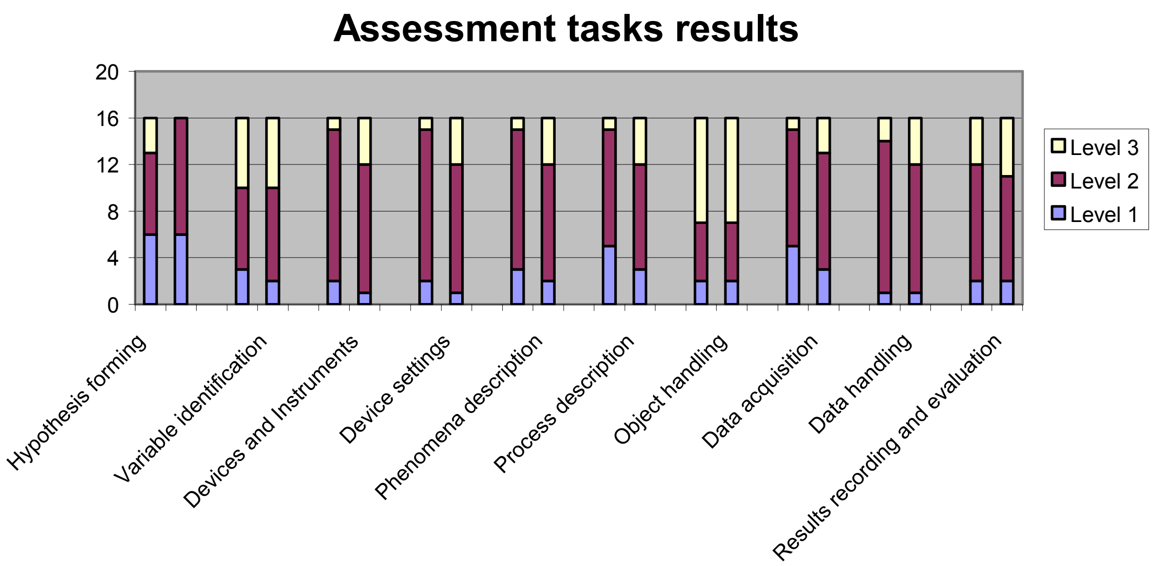

Figure 3. *Results for the first task (small resistance measurement, left bars at each skill) and the second task (large resistance measurement, right bars at each skill)*

DISCUSSION, CONCLUSIONS AND IMPLICATIONS

Our findings indicate that virtual environments and OLLE in particular may be effective in supporting the development of students' experiment design abilities. This can be attributed to several factors. First, they provide teachers with a powerful environment with which they can design, develop and apply inquiry-based investigative activities promoting scientific experimentation. Second, they provide students with a technologically rich environment with which they can interact by life-like manipulations of virtual objects being engaged actively in "doing science" and develop their experimental skills. Third, virtual environments present a simplified view of the world by omitting elements which are not essential to the phenomena under study. Thus students are relieved from time-consuming real lab manipulations (Psillos & Niedderer 2002) and focus their attention on the relevant objects and properties and are facilitated in making decisions about experiment design and applying it. As Lefkos et al. (2011) remark, virtual environments, like OLLE "can be considered as providing scaffolding to students to help them carry out such guided activities and develop design skills". We consider that our findings are in line with other results in other areas and extend these results to the field of electric circuits.

HOW SECONDARY SCHOOL STUDENTS DESIGN, PERFORM AND EXPLAIN EXPERIMENTS ON THE RATE OF REACTION

Montserrat Tortosa Moreno [1]
[1]Departament de Didáctica de les Matemàtiques i les Ciències Experimentals,
Centre de Recerca per a l'Educació Científica i Matemática. Universitat Autònoma de Barcelona.

Abstract: The design of scientific experiments has the challenging issue that in some cases theoretical variables have to be translated into manageable and observable variables in the experiment. Secondary school students' achievements when they are faced to the design of an experiment to change the rate of a chemical reaction are studied. Pupils came from different schools to participate in an inquiry designed chemistry workshop at the university. Our results show that most of them are able to choose a correct variable and to identify more than one variable that could affect the rate of the reaction. We have also found that students design and perform a wide variety of experiments using both classical tools and microcomputer based laboratory equipment. A remarkable finding is that a considerable amount of learners have problems when transferring the concept of efficient collision to a different context. We suggest that presenting other contexts to students and analysing their outcomes can be helpful to design activities to scaffold students to achieve the competency of designing experiments.

Keywords: Design of experiments , transference of concepts between contexts, chemistry laboratory, control of variables, secondary school students.

1) BACKGROUND AND FRAMEWORK

Mastering procedures such as the design of experiments and the control of variables is an essential skill in scientific research, and so, it is a part of scientific literacy (PISA, 2006). To improve this knowledge, students need opportunities to practice selected skills, and laboratory activities if their design is accurate, can be a useful tool for this.

Research on the efficacy of chemistry laboratory activities have been conducted, and there is agreement that inquiry-centred tasks enhance meaningful student learning (Hofstein & Lunetta, 2004; Aksela, 2005; Hofstein, et al, 2005; Minster & Krauss, 2005; Tortosa, Pintó & Saez, 2008). Some studies have reported that younger pupils did not produce explanations for phenomena about chemical change that were consistent across contexts (Watson et al., 1997, Cackmacky et al 2006).

The design of scientific experiments has the challenging issue that, in some cases, theoretical variables have to be translated into manageable and observable variables in the experiment. It has been found that primary school students (Kanari & Millar, 2004) can design and interpret the results of science experiments in an inquiry-guided task, if with some inaccuracies.

One of the core concepts in chemical education is the *rate of reaction,* crucial in the chemical industry. We found no relevant research studies analysing how secondary school students use this concept to design chemistry experiments in an inquiry-guided task. In our work, students' achievements were studied when they were faced with the design, performance and explanation of an experiment on the rate of reaction.

Purpose and Research Questions

We understand that learning of a concept has occurred if there is the possibility to apply the knowledge to new situations. As we wanted to know to what extent students have learned the variables that control the rate of reaction, our research questions were:

-Are secondary school students able to apply the collision theory in a concrete context by choosing a variable in order to design an experiment to change the rate of a reaction?

-To which extent can students identify and take into account other variables that can affect the results of their experiment?

2) RATIONALE

The main interest of this work was to investigate the features of the design of chemistry experiments by secondary school students, especially the control of variables and the transfer of concepts between contexts. The design of experiments is crucial in scientifically literate pupils, and there has been little research on this issue in chemical education. Our students were taught the collision theory, and then were asked to design experiments to change the rate of a reaction. Students had to transfer their knowledge to a specific heterogeneous reaction that released a gas and, simultaneously, they had to consider the subsequent control of variables and choose adequate tools to obtain the required data. Students were scaffold with orienting questions in their worksheets.

3) METHODS

The research was conducted with 104 chemistry students (15-17 years) belonging to six groups from four secondary schools in Catalonia (Spain) attending a four-hour chemistry workshop in an inquiry-guided learning cycle at the university. Three of the groups were formed by students in their last year of secondary school compulsory education (15-16 years old) taking the optional subject “Physics and Chemistry” at their schools. The other three groups corresponded to pupils in their first year of post-compulsory education (16-17 years old) taking “Chemistry” as an optional subject.

Students had to solve a contextualised problem in which the understanding of the chemical concept “rate or reaction” was crucial for solving the task. The workshop was designed as a leaning cycle, starting with activities to make students’ previous ideas explicit. Students from different schools had been taught about collision theory differently. Pupils were asked to design and to perform an experiment in order to increase the rate of carbon dioxide production obtained by the reaction of calcium carbonate and hydrochloric acid. The author of this research was the teacher who monitored the sessions where students, working in small groups, received support. Former laboratory worksheets were tested with previous groups of students and changes were made to provide the students with adequate time and support. More specifically, pupils were guided with the following questions:

a) Which factor have you chosen to investigate its effect on the rate of reaction?
b) Design the experiment you would perform to test your ideas, and explain it briefly.
c) What are the other variables that can affect the rate of reaction?
d) What will you do to avoid their influence in your experiment?

We analysed the student’s answers to questions a-d in the lab sheets.

4) RESULTS

The analysis of the answers obtained to questions a), c) and d) are summarised in Table 1.

School		A n = 21	B n = 22	C n = 18	(15-16 years old) A+B+C n=61	D n = 23	E n = 11	F n=9	(16-17 years old) D+E+F n=43	Total n =104
Variable chosen	Temperature	11	11	10	**32**	4	5	3	**12**	**44** (42%)
	Concentration	5	--	3	**8**	6	2	4	**12**	**20** (19%)
	Surface contact	3	8	2	**13**	13	4	2	**19**	**32** (31%)
	Other/N.A.	2	5	3	**10**	--	--	--	--	**10** (10%)
Mention other correct variables		18	13	17	**48**	23	11	9	**43**	**91** (88%)
Mention incorrect variable (pressure)		6	10	5	**21**	20	0	3	**23**	**44** (42%)
Correct explanation of control of variables		11	10	11	**32**	19	8	4	**31**	**63** (61%)
Incorrect explanation of control of variables		0	0	1	**1**	3	--	3	**6**	**7** (7%)
No explanation of control of variables		10	12	6	**28**	1	3	2	**6**	**34 (33%)**

Table 1. Variables evaluated by students in their experiments on the rate of reaction between $HCl_{(aq)}$ and $CaCO_{3(s)}$

From this table, we observed that most students (90%) correctly chose the variables to test for their influence on increasing the rate of reaction: increased temperature, increased concentration of hydrochloric acid and increased surface of contact (calcium carbonate in smaller pieces). Most of the students (88%) mentioned the other correct variables. We observed that the frequency of the selection of each variable was similar in each group of older students, whereas the younger ones chose mainly temperature.

A remarkable result was that a considerable proportion (44%) of the students incorrectly stated that changes in pressure could affect the rate of the reaction. One possible explanation to this outcome may be the fact that, in the workshop, students were taught collision theory with the example of efficient collisions in gases (where pressure can vary the speed of the reaction) and they transferred this knowledge incorrectly to the new situation (the reaction between a solid and a liquid). Our results point out difficulties in transferring concepts between different contexts, as other authors have (Watson et al., 1997, Cakmakci et al 2006). Our results also suggest a difficulty in relating the macro and submicroscopic levels, as found by Justi (2002).

A great variety of answers were found in the analysis of question b: some students made drawings, other wrote text, some used microcomputer-based laboratory equipment (Tinker, 1996) and some used classical equipment. We found no relevant differences between the groups of students. An example of students' explanations, using classical equipment and microcomputer-based equipment, is shown in Figure 1.

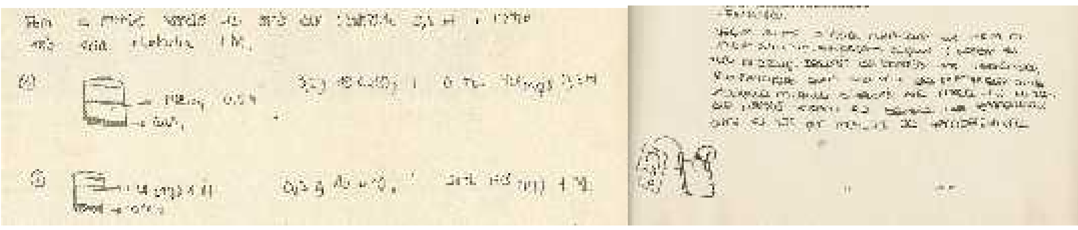

Figure 1. Examples of a student's explanation (in Catalan) when designing an experiment to test if a specific variable influences the rate of the reaction between $HCl_{(aq)}$ and $CaCO_{3(s)}$.

5) CONCLUSIONS AND IMPLICATIONS

From our results, we have found that when secondary school students are faced with designing an experiment on the rate of a reaction, the majority of students are able to recognise more than one variable which can influence the experiment. The way in which students explain the control of variables varies to a large extent from writing to drawing. More than half of the students performed the task correctly. We also observed that the correct explanation of the control of variables was done in a slightly higher proportion by post-compulsory students. We agree with other researchers (Cakmakci et al, 2006), interpreting this as a sign of general maturity in grown-up pupils. Finally, we detected a difficulty in understanding efficient collision and the factors that influence it in different chemical reactions, as nearly half of the students mentioned variables which would not increase the initial rate of the reaction. We think that more research should be done by presenting other contexts to students and analysing their interpretation of experiments in order to help students achieve competence in designing experiments.

TYPES OF INTRA- AND INTERMOLECULAR BONDING: THE CASE OF GENERAL CHEMISTRY TEXTBOOKS

Georgios Tsaparlis and Eleni T. Pappa [1]

[1]University of Ioannina, Department of Chemistry, GR-451 10 Ioannina, Greece

Abstract: In this study we identify and compare the teaching of chemical bonding in terms of the ordering and extent of coverage of the various relevant concepts and bonding types. To this purpose, we examine a number of general chemistry textbooks. Fourteen books made the convenience sample for the comparison. Similarities and differences were identified with regard to the following aspects: presentation order of intra-molecular bonds; placement and method of presentation of inter-molecular bonds; the bond continuum; physical states and their connection with the types of bonding; metallic bonding; the octet rule; electronegativity and bond polarity; semi-covalent (dative covalent) bond. Almost all books present intramolecular before intermolecular bonds; more books start with ionic bond, than with covalent bond; most books refer to the covalent and ionic bonding continuum, while few books treat the two types as autonomous; electronegativity and bond polarity are presented within intramolecular bonding; most books consider only intramolecular bonding as true chemical bonding. Finally: most textbooks do not mention the semi-covalent (dative covalent) bond; most textbooks include the metallic bond. Regarding the intermolecular bonds, the books follow different orders of presentation, while some books pay more attention to hydrogen bonding. This article concludes with considering the way chemical bonding is treated by the states-of-matter approach (SOMA) of introductory chemistry.

Keywords: general chemistry textbooks, types of chemical bonds, intramolecular bonding, intermolecular bonding, chemical bond continuum

BACKGROUND AND FRAMEWORK

Chemistry education should aim at two main targets: to provide students with: 1) chemical literacy; 2) chemical culture. In addition, it must cultivate higher-order cognitive skills and reveal the process of science. It is therefore important to show that chemistry is not only a useful, but also an interesting and aesthetically enjoyable subject. The purpose of this study is to identify and compare the teaching of chemical bonding in terms of the ordering and the extent of coverage of the various bonding types and the relevant concepts. To this purpose, we examined a number of general chemistry textbooks.

According to Gagné (1985), learning tasks can be organized in a *hierarchy* according to complexity. The primary purpose of the hierarchy is to guide instructors so that they can "identify prerequisites that should be completed to facilitate learning at each level" (Kearsley, 1994). This learning hierarchy also provides a basis for sequencing instruction**.** Kearsley suggests keeping the following principles in mind: (1) learning hierarchies define a sequence of instruction; (2) learning hierarchies define what intellectual skills are to be learned; (3) different instruction is required for different learning outcomes.

Rationale: Teaching Chemical Bonding

Four general types of bonds are traditionally employed in the teaching of chemistry: ionic, covalent, molecular, and metallic. Each type is used with the aim to rationalize the properties of a group of compounds. This approach is due partly to the fact that it is deemed convenient for students, and partly to historical reasons. It also allows for the statement of well-defined questions for the exams. The approach leads to an oversimplification and a generalization, which constitute obstacles to conceptual understanding and good learning: there are many groups of modern materials that cannot be classified into any of the above four types of bonding.

Covalent and ionic bonds are often presented in a dichotomous manner as due either to the sharing or to the transfer of electrons. The case of pure covalent bonding appears in the case of homonuclear bonding. However, a pure ionic bond does not exist. In heteronuclear systems, bonding is better described by means of a continuous covalent-ionic scale. In addition in ionic crystals, the concept of molecule in the context of "two atoms bonded together by an ionic bond" does not exist: ionic bonding is extended instead across the three-dimensional crystal, so that any two neighboring ions of opposite charge are bonded (Taber, Tsaparlis, & Nakiboglu, 2011). The establishment of the above dichotomous approach hinders understanding of a more complex scale.

Traditionally, bond polarity is discussed in the context of covalent bonding only, and not as an integral part of bond polarity. The difference in electronegativity between the two atoms participating in a bond is used as a criterion for predicting bond type. The usual approach to metallic bonding (a lattice of metal ions in a sea of electrons) might contribute to oversimplification and generalization. On the other hand, the octet rule is another 'fetish' that hinders the understanding of molecules and bonds with more or less than eight electrons in the outer shell of the atoms. Finally, in most books covalent and ionic bonding is described as true bonding, while the Van der Waals bond and hydrogen bonding are presented just as 'forces'.

It is noteworthy that while in practice a theoretical approach to bonding is adopted as a rule, a teaching methodology that will be consistent with Gagné's theory (as well as other theoretical approaches, such as Ausubel's meaningful learning or active learning methods) requires the coupling of the theoretical models with experimental data. For instance, Nelson (1994) distinguished three "limiting types" of binary compounds: metallic, salt-like (ionic), and non-metallic, with each type being characterized by a given electrical character; these represent extremes, and most binary compounds fall somewhere in between these extremes.

Finally, a new 'bottom-up' framework for teaching chemical bonding has been proposed recently by the Weizmann team (Kronik, Nahum-Tami, Mamlok-Naaman, Hofstein, 2008)): a single atom—elemental principles: the chemical bond—fundamental principles; bonds—a continuum approach; structures; properties. A main feature is the continuum approach in dealing with bonds.

PURPOSE AND METHOD

In this study, we evaluate the presentation of chemical bonding in a number of general chemistry textbooks. In particular we look for similarities and differences with regard to the following: order of presentation of intramolecular bonds; the covalent/ionic bond continuum; ionic bond (energy diagram, the octet rule, crystal structure, properties, Coulomb's law, electrostatic nature, Lewis structures); covalent bond (energy diagram, the octet rule, crystal structure, properties, Coulomb's law, electrostatic nature, Lewis structures; electronegativity; the octet rule; semi-covalent (dative covalent) bond; metallic bond; order of presentation of intramolecular bonds; physical states and their connection or no connection with the types of bonding.

At the outset, we should state that the aim of this study is not to carry out an evaluation of the particular general chemistry textbooks. We are simply interested in looking for patterns. Fourteen general chemistry books were analyzed, making the convenience sample that was drawn from the Library of the University of Ioannina. The books are as follows:

1. Atkins & Jones (2001). Chemistry: Molecules, matter and change, 4^{th} edn.
2. Chang (2000). Chemistry, 6^{th} edn.
3. Ebbing & Gammon (1999). General chemistry. 6^{th} edn.
4. Gymer (1973). Chemistry: An ecological approach.
5. Kotz & Treichel (2003). Chemistry and chemical reactivity, 5^{th} edn.
6. Lewis & Evans (1997). Chemistry, 1^{st} edn.
7. Pauling & Pauling (1975). Chemistry.
8. Rosenberg & Schaum (1966). College chemistry, 5^{th} edn.
9. Schwartz, Bunce, Silberman, Stanitski, Stratton, & Zipp (1997). Chemistry in context / Applying chemistry to society.
10. Sherman & Sherman (1993). Chemistry and our changing world, 3^{rd} edn.
11. Silberberg (1999). Chemistry - The molecular nature of matter and change, 2^{nd} edn.
12. Spencer, Bodner, & Rickard (2008). Chemistry - Structure and dynamics, 4^{th} edn.
13. Timberlake (2002). Chemistry - An introduction to general, organic and biological chemistry, 8^{th} edn.
14. Whitten, Davis, & Peck (1999). General chemistry, 6^{th} edn.

RESULTS

Almost all fourteen books present intramolecular before intermolecular bonds.

Presentation order of intramolecular bonds:

- 10 books start with ionic bond, while
- 4 textbooks start with covalent bond.

Intramolecular bond continuum:

- 11 textbooks refer to the covalent and ionic bonding continuum.
- 3 textbooks treat the two types of bonding as autonomous types.

Ionic bond:

- Only 2 textbooks include the potential energy diagram for ionic bond.
- 10 books refer to the formation of the ionic bond, but only 4 use the octet rule to explain the formation of ionic bond.
- 7 textbooks refer to the accepted model that ionic compounds create crystal structures with ionic bonds.
- 5 books refer to lattice enthalpy.
- 8 books refer to ionization energy and electron affinity.
- 7 books refer to electronegativity and explain with it polarity of ionic bonds.
- Coulomb's law is included in 4 books.
- The electrostatic nature of ionic bond is discussed in 8 books.

- In 3 books, Lewis structures are discussed in connection with the ionic bond.

Covalent bond:

- 3 textbooks include the potential energy diagram for covalent bond.
- 8 books refer to the octet rule as the cause of covalent bond formation, while the remaining
- 6 books consider the octet rule as a guiding rule, and not as the cause of bond formation.
- 9 textbooks include that covalent compounds create molecular structures with covalent bonds
- 2 books refer to ionization energy and electron affinity in connection with covalent bonding.
- 6 books refer to electronegativity with the aim to explain covalent bond polarity, while
- 7 books refer to bond polarity in connection with polarity of intramolecular bonds in general.
- 2 books include Coulomb's law in connection with covalent bonding.
- Lewis structures are included in 7 books (with 1 book not mentioning the bonding electron pairs in covalent bond formation)

Additional features:

- 11 textbooks do not include the semi-covalent bond.
- 6 books refer to metallic bond after the study of intra- and intermolecular bonding.
- 4 books refer to the metallic bond after the study of intramolecular bonding, but before presenting intermolecular bonding.
- 1 book, while referring to the concept of metallic bonding, it does not invoke the term metallic bond. Finally,
- 3 books do not refer at all to metallic bonding.

Intermolecular bonds:

- 1 book presents intermolecular bonds without referring to their types;
- 4 books refer to the existence of intermolecular bonds but describe only the hydrogen bond;
- 9 books follow different orders the types of intermolecular bonds.

Physical states and chemical bonds:

- 4 books refer to physical states without any connection with bonding.
- 1 book refers to physical states after introducing the bonds.
- 4 books discuss physical states after the introduction of intra-, but before discussing intermolecular bonds.
- 1 book discusses physical states within intramolecular bonding.
- 1 book refers to intermolecular bonding when discussing the liquid state, while the two other physical states are discussed in a following chapter; on the other hand,
- 1 book refers to the gaseous state before introducing intermolecular bonding, while the two other physical states are discussed immediately afterwards.

CONCLUSIONS AND IMPLICATIONS

Almost all books present intra- before intermolecular bonds. Most textbooks present first the ionic bond; most textbooks refer to the covalent/ ionic bonding continuum; most books consider only intra-molecular bonding as true chemical bonding, while intermolecular bonds are described as *forces*. Bond polarity is connected directly with covalent bonding. In few cases bond polarity is discussed at the beginning or at the end of the chapter on bonding. Electronegativity is presented in the context of polar covalent bonds, and not always as an integral part of bond polarity. Differences in electronegativity of the bonded atoms are used for identifying bonding as covalent or ionic. In most books the octet rule is presented as a prerequisite for the realization of bonding both covalent and ionic. Finally, in few books ionic and covalent bonds are presented as autonomous bonds, while the rest emphasize the existence of both an ionic and a covalent character in the majority of compounds.

Conclusions for the ionic bond: In their study of the ionic bond, most textbooks refer to: the crystal structure of ionic compounds; the electrostatic nature of the ionic bond; the formation of octets; ionization energy and electron affinity. Also: most textbooks do not refer to: the octet rule, Lewis structures, and the Coulomb law; the lattice enthalpy; electronegativity; the potential energy diagram.

Conclusions for the covalent bond: In their study of the covalent bond, most textbooks refer to: the molecular structure of covalent bond; Lewis structures; the octet rule. Also: more textbooks in covalent bond than in ionic bond are talking about electronegativity and bond polarity. And in most textbooks there is no reference to the ionization energy and/or the potential energy diagram in connection with covalent bonding.

Finally: most textbooks do not mention semi-covalent (dative covalent) bond; most textbooks include metallic bond. Regarding the *intermolecular bonds*, the books follow different orders of presentation of the types of these bonds, while some books pay more attention to hydrogen bonding.

Bonding in the States-Of-Matter-Approach (SOMA)

Before we conclude, we will comment on the treatment of chemical bonding taken by the States-Of-matter Approach (SOMA) to introductory chemistry. In SOMA, there are three major units, namely: (A) Air, Gases and the Gaseous state; (B) Salt, Salts, and the Solid State; (C) Water, Liquids, and the Liquid State. A textbook has been written that adopted SOMA, and this book is presented and evaluated in another article of these Proceedings (Tsaparlis & Pyrgas, ESERA 2011 Proceedings). The structure of SOMA dictates the order of presentation of intermolecular and intermolecular bonds.

The elements and compounds which, under usual conditions, are in the gaseous state, have small and simple covalent molecules (H_2, O_2, N_2, halogens, noble gases, H_2O, O_3, NH_3, NO_x, CO, CO_2, gaseous hydrocarbons, H_2S, SO_2, HCl). It follows that we have to start with the covalent bond (Johnstone, 2000; Johnstone, Morrison, & Reid, 1981). In the case of the ideal gas, intermolecular forces are absent, but Van der Waals bonds and London dispersion bonds can be introduced with real gases. In this way, we deal quite early with both intra- and intermolecular bonds. In the unit of solids, we start with table salt, the ionic bond, and crystal structure. Later, we deal with molecular solids, metals and the metallic bond; hydrogen bonding is also mentioned in the structure of ice. Finally, in liquids, we return to London dispersion, Van der Waals, and hydrogen bonding; in addition, we deal with aqueous solutions of electrolytes, including acids, bases, and salts; here we distinguish between: on the one hand, the dissociation of ionic compounds into their constituent ions in water; and on the other hand, the complete or partial ionization of covalent compounds in water (strong and weak acids and bases).

Turning to the *implications* of the findings of this study, we emphasize the need for the treatment of the various types of intra- and intermolecular bonds as a continuum. Needless to add the need for more research in order to reach improved methods of teaching and learning about chemical bonding. We are of the opinion that the SOMA method fits intra- and intermolecular bonds in a logical manner and contributes to the bond-continuum approach; further research is also needed here.

Abstract: This group of papers explores the development of student understanding and application of the discursive tools of science to reason in this subject, as the basis for classroom practices that parallel scientists' knowledge production practices. We explore how this account of the disciplinary literacies of science can be enabled through effective pedagogies. The papers draw on research from Australia and Sweden that have overlapping agendas and theoretical perspectives including pragmatism (Peirce 1931-58; Dewey 1938/1997), social semiotics (Kress et al. 2001) and socio-cultural perspectives on language and learning (Lemke, 2004). The papers examine the role of language/multimodal representations in generating knowledge claims in science classrooms, the classroom epistemologies that support learning, and assessment practices from this perspective. A large body of conceptual change research has identified trenchant problems in conceptual learning in science, spawning long-standing and ongoing programs to identify pedagogies to address this. By redefining the problem in terms of language and representation, we aim to offer a way forward to support student engagement and learning in science.

Keywords: Student learning in science, representation, pragmatism, socio-cultural perspectives, epistemic

BACKGROUND, FRAMEWORK AND PURPOSE

Much conceptual change research has identified trenchant problems in conceptual learning in science, spawning various long-standing programs to address this (Treagust & Duit, 2008). However, conceptual change perspectives are also changing to accommodate complexities uncovered by recent research and new theoretical perspectives (Vosniadou, 2008). Recent work in cognitive science (Klein, 2006; Tytler & Prain, 2010) emphasizes knowledge and learning as fundamentally situated, strongly dependent on perceptions and perceptual processing (Barsalou, 2003) and on informal reasoning, including pattern completion, association, and model based reasoning (Lehrer & Schauble, 2006a). Part of this work recognizes the fundamental role of language and representation as constituting thought rather than being a by-product of internal, stable mental constructs. There is increasing interest in socio-cultural theories that frame learning in terms of induction into the discursive practices through which the science community generates and validates ideas about the world (Lemke, 2004). From this perspective, learning and knowing is not primarily thought of as the inculcation, through formal logics, of uniquely and verbally defined conceptual entities, but rather as a process of increasing mastery of the multi-modal discursive tools and practices used by the scientific community.

Researchers have focused extensively on learning through inquiry, in representing investigative processes of science in the classroom to capture student engagement through exploration of ideas. This symposium explores a pragmatist, semiotic perspective on teaching and learning that brings notions of product and process together. From this pragmatist perspective (Peirce 1931-58; Dewey 1938/1997), knowledge and learning derive their meaning from their use, and conceptual entities are profoundly contextual in nature. These ideas are captured in recent work on the nature of science in which the existence of an irreducible 'scientific method' has been questioned and science is seen as a human practice, responsive to the contextual communicative needs of research laboratories and wider communities of practice (Duschl & Grandy, 2008).

The three papers in this symposium are grounded in larger Australian and Swedish research programs exploring with teachers the implications of these theoretical ideas for teaching, learning and assessment in science. The projects are strongly grounded in pragmatist perspectives, drawing on Peirce (1931-58), and Dewey (1938/1997), and on socio-cultural perspectives that view learning as induction into the epistemic practices of science through its multi-modal discursive tools (Lehrer & Schauble, 2006b; Lemke, 2004). The programs are aligned broadly with social semiotic perspectives (Kress et al., 2001), but the Australian project in particular focuses on student generation and negotiation of representations as a basis for quality reasoning and learning (Ford & Forman, 2006; Greeno & Hall, 1997). In this way, student engagement with the epistemic practices of science is seen as a fundamental condition for quality learning. Thus, the symposium explores linking the epistemic practices of science, the nature of conceptual learning, and classroom epistemological processes, to enable quality learning.

METHODS

In each paper we report on empirical classroom results based on video capture of student and teacher interactions, and use discourse analysis to understand the nature of the interactions between teachers, student, and artefacts that lead to quality learning. In the Australian cases the data also included interviews with students and teachers, pre and post tests, and student-produced artefacts. The analyses will explore:

1. The key features of a pedagogy based on student generation and negotiation of representations, and how such a pedagogy works to support quality learning;
2. The possibility of using semiotic resources to establish continuity between proximate and ultimate scientific learning purposes; and
3. The implications of a representational perspective for assessment in science.

STUDY 1: LEARNING SCIENCE THROUGH REPRESENTATIONAL CONSTRUCTION

Background, Framework and Purposes

Learning science in school is now broadly understood as learning the literacies of a specific discourse community, using a range of subject-specific and general representational tools to construct and justify evidence-based claims about the natural world (Kress et al. 2001;

Lemke, 2004). Researchers in classroom studies where students were guided to construct their own representations of scientific ideas (Carolan, Prain & Waldrip, 2008; Ford & Forman, 2006; Greeno & Hall, 1997) have noted the importance of teacher and student negotiation of representational meaning and of students having opportunities to explore, elaborate, re-represent and coordinate representations to interpret science phenomena. There is growing evidence (Hubber, 2010; Hubber, Tytler & Haslam, 2010;) of increased student engagement and improved learning outcomes from these processes. This paper reports on aspects of an Australian project where the researchers worked with teachers to develop and validate a pedagogy based on student generation and negotiation of representations. Research questions include: 1) What are the key features of a pedagogy based on student generation of multi-modal science representations? 2) How does this pedagogy support student reasoning in science, and 3) What evidence is there that this approach improves students' conceptual learning?

Methods

The research team worked with four experienced primary and secondary teachers to develop a series of teaching sequences on science topics that the conceptual change literature has shown to present learning difficulties. The sequences focused explicitly on student generation and negotiation of representations related to key concepts. In working with the teachers over two years, we developed a set of pedagogical principles based on our experience and on the theoretical ideas described above. The teachers' practices, student-teacher interactions, and student activity and discussion were monitored using classroom video capture. Key lessons were coded using an emergent scheme generated using Studiocode software, to make apparent the patterns of pedagogical moves and to explore the key features that could be considered fundamental to a representation-intensive pedagogy.

Teaching and learning sequences were selectively transcribed and subjected to ethnographic analysis to identify the extent to which, and in what ways, the pedagogical principles were exemplified, and for evidence of ways in which the focus on representational clarification supported reasoning and learning about key science ideas. Students were interviewed about their learning, and teachers about their perceptions of the effectiveness of aspects of the sequence. Student workbooks were collected to provide a continuous record of representational work. Pre- and post- test data were analyzed for evidence of improved understanding, flexibility representation generation, and capacity to transfer ideas to other relevant phenomena.

Results

The pedagogy has the following key principles:

1.The sequencing of representational challenges involving students generating representations to actively explore and make claims about phenomena, involving a) identifying appropriate representations underpinning key concepts; b) establishing a representational need, and c) working towards alignment of student generated and canonical representations.

2. Explicit discussion of representations, including a) their selective purpose, b) group agreement on generative representations, c) form and function, and d) the adequacy of representations.

3. Meaningful learning through representational/perceptual mapping between objects/events and representations

4. Ongoing and summative assessment focusing on the adequacy and coordination of representations.

Moreover, analysis of the patterns of conceptual clarification and orientation, representational challenges, clarification and negotiation of representations, and explanation/resolution showed similar pathways for lessons but differences depending on year level, place of the lesson in the sequence, and topic.

Analysis of teacher/student exchanges and student artifacts demonstrated a strong alignment of the pedagogy with inquiry principles, but with strong framing of representational exploration leading to appreciation of canonical forms.

We argue that this constraint on inquiry offers a productive way forward for classroom practice that relates the exploratory, epistemic practices of science, needing to represent the canonical knowledge forms as a key target for science curricula. Lesson transcripts, interviews, and post-test results are used to show evidence of significant reasoning and learning. The analysis of reasoning is linked to the use of representations as epistemic tools in science knowledge-building, and draws on Peirce's (1931-58) triadic model of meaning making, and notions of affordances to identify the way representations selectively focus and constrain attention on aspects of the problem space. Teacher framing of the use of multiple, selective representations and student understanding of the partial and selective nature of representations will be illustrated.

Conclusions and implications

There is increasing agreement that learning involves a process of induction into specific discipline-based discursive practices, and is mediated by representations as the epistemic tools of science. This research represents a serious attempt to translate these theoretical insights into a practical classroom pedagogy that can effectively frame learning in science. This program has both practical significance for teacher practice and teacher education, and theoretical significance in bringing science classrooms and science practice into closer alignment. A re-interpretation of conceptual problems in learning science in terms of representational issues, and a program to translate this into a pedagogy, shows promise of addressing problems in learning science that are well established in the conceptual change literature.

STUDY 2: USING ORGANISING PURPOSES TO SUPPORT SEMIOTIC RESOURCE USE IN SCHOOL SCIENCE

Background and Aims

In this study we discuss how educational research in semiotics and on representation use in science classrooms can be supported by a pragmatically-oriented approach to science education research. The aim is to demonstrate a heuristic that can be used to support teachers in scaffolding students' conceptual learning and agency in science subjects. The unit of analysis is action and activities (including talk and the use of other semiotic resources), rather than mental entities, and hence important aspects of learning are studied as visible processes in communication and interaction as mediated by different semiotic resources and artefacts (Kress et al 2001; Säljö & Bergqvist 1997).

In this study we supplement earlier research within this field with the pragmatist notion about how the progression of learning can be understood as oriented by *proximate purposes*, which the teacher needs to make continuous with the *ultimate purposes* of an educational sequence jointly with the students (Johansson & Wickman, 2011; Wickman & Ligozat, 2011). These two kinds of purposes make up the *organising purposes* of a teaching sequence.
The ultimate purposes or aims belong to the new kinds of scientific practices with concepts that are not yet familiar to the students (here we illustrate the concepts of friction, motion and

force as such ultimate purposes of a lesson). The proximate purposes belong to activities where students are given more familiar topics to study and discuss. A proximate activity of relevance for the ultimate aim of learning about friction and motion is for instance why we have tyres on our cars. Dewey, (1938/1997) called such proximate purposes that make sense and give agency to the student *ends-in-view*. A key task for the teacher is to find proximate purposes that work as ends-in-view to the students and that the teacher also can make continuous with the ultimate purposes of the lesson. The ultimate purposes make sense to the teacher, but the teacher has to translate them and make the students understand how the activity with ends-in-view also deals with the ultimate purposes. The praxis of using ends-in-view is commonplace in teaching, although their continuity with more ultimate goals of science teaching is rarely examined by educational researchers. The concept of ends-in-view originates from Dewey's (1938/1997) thinking about progression ("growth" in Dewey's terminology) as creating continuity between the prior experiences of students (including their use of semiotic resources), the current situation, and the new kinds of practices, concept uses and semiotic resources that students are introduced to. Our research questions in this study are: (1) How are the students' and teachers' language use, semiotic resource use and experiences made continuous in two different classrooms? (2) How may a teacher use the organising purposes to support this continuity for learning in science?

Methodology

In this paper we analyze two teaching sequences. The first is from a Swedish Year 5 school class studying science (Johansson & Wickman, 2011), which give a full analysis of the conversations in the class. The ultimate learning purpose for the lessons is about how friction facilitates or impedes motion. The teacher introduces this through more proximate purposes. We have studied two such proximate purposes used by the teacher: 1) why cars have tyres, and 2) that a vehicle can continue to travel indefinitely if there is no resistance at all. Events in the classroom were filmed and transcribed. The second analysed teaching sequence is from an Australian study using representations as semiotic resources to introduce the concept of force in Year 7 (Hubber, Tytler & Haslam, 2010; Hubber, 2010). We coded situations in the classrooms as dealing with either proximate or ultimate purposes and the associated semiotic resources as *colloquial language, inter-language, and science language*. The idea of continuity between the every-day and scientific uses of language has been developed by Wallace (2004) and Olander (2010). As the method for analysing the continuity regarding the organising purposes effected by the semiotic resources and experiences related to in the classroom we used Practical Epistemology Analysis (PEA), which is based on Dewey's (1938/97) ideas, and broader investigations into language and action (Wickman & Östman, 2002).

Findings

The Swedish classroom study demonstrates how the teacher first creates a situation where the proximate purpose of *why we have tyres on our cars* functions as an end-in-view to the students and helps them to take part in the conversation. The predominance of student experiences and student language in the conversation helps make it possible for students to understand why we have tyres on our cars. A short excerpt from the conversation illustrates this:

Teacher:	But what did you have to say about this, why do you think that we have tyres on our cars then? That's interesting, is it not, especially now that different ideas are floating around? Yes!
Erik:	Because otherwise we won't get anywhere, I mean then we get a grip, because without, if you didn't have that rubber on the tyres, then you'd just move around, you wouldn't get any, anywhere.

However, during the rest of the conversation about why we have tyres on our cars the teacher does not relate the proximate purpose to the ultimate purpose, so the students are not offered the possibility of seeing how only certain aspects of what is treated from the proximate purpose are relevant to the ultimate one about friction. In the conversation the two organising purposes are not made continuous in the sense that the concepts of friction and motion are related to the student experiences and word usage (e.g. grip, move around) regarding why we have tyres on our cars.

Neither in the second situation, about *how a vehicle can continue to travel indefinitely if there were no friction*, are the proximate and ultimate purposes clearly related to each other in the conversations between the teacher and the students. This conversation starts like this:

Teacher:	So friction makes it, it stop, this resistance, so that it doesn't continue for ever. If there wasn't any resistance anywhere, air resistance like you have felt with the car and no resistance on the road or in any of these parts, then these vehicles when they are given a push, they would continue for ever.
Erik:	Would they do that then?!
Teacher:	Yes! If there wasn't any resistance anywhere. Then this force that the vehicle has received would continue for ever.
Erik:	What if there is an uphill slope?
Teacher:	Yes then there'd be resistance immediately, right.
Erik:	Yes, exactly!

The students do not construe relationships jointly with the teacher about how the experiences and words used by the students in relation to the proximate purpose also relate (or do not relate) to the ultimate purpose about how friction facilitates or impedes motion. The teacher uses the word friction and chooses the term *resistance* as an inter-language, but no continuity is established to the ultimate purposes, which allows the students to use their own chosen colloquial words, the inter-language concept of resistance, and the scientific terms friction and motion to make them continuous in communication and action.

This non-continuous situation is contrasted with the one in the Australian classroom concerning how a teacher introduces the topic of how forces affect objects (an ultimate purpose) with the help of a clay-like material, plasticine. The students were asked to change the form of plasticine (a proximate purpose) and to give the words that they can use to describe what they were doing with the plasticine, such as stretch and roll (colloquial language). Doing this task represents one proximate purpose, which is followed by others. Together with the students, the teacher then sorts their words under the headings of "pull" and "push" (inter-language) and how all their different changes to the plasticine can be understood as "pull" or "push", which together represent what physicists call "force" (science language). The students and the teacher then work to create diagrams using arrows (semiotic resource) that in a communicative way can help other students to form plasticine to a certain shape (to mediate action through semiotic resources). These arrows at the same time function as a sort of inter-language (arrows that show the direction of force in physics vs. arrows as directions for shaping the plasticine). When the teacher asks the students about the best choice of representation, student 2. highlights its purposefulness:

Teacher:	Which one of these representations worked well in explaining what was done?
Student 1:	John's because it showed you exactly what to do. Mine could have ended up anything.
Student 2:	It was more visual, you can actually see it is easier to actually see what you did. With the other ones you could make it in different ways.

The semiotic resources are used by the teacher in this Australian study in a way that helps to create continuity because 1) the proximate purposes (shaping plasticine and giving other students instructions about how to give it a specific shape) gives students an activity where they can see an end-in-view, and 2) the semiotic resources are formulated explicitly by the teacher together with the students in such a way as to create continuity between the ends-in-view and the ultimate purpose of teaching students about the concept of force and how it can be represented.

Significance of Findings

Students do not learn scientific concepts simply because the teacher adopts an inter-language, but rather the students use their own experiences and a variety of semiotic resources. The use of these meaning-making resources needs to be closely monitored in relation to the continuity it creates to the proximate purposes, ends-in-view, and ultimate purposes of lessons. Hence, teachers can use the two organising purposes as a heuristic to support science learning by planning for and monitoring their continuity in the sequence of classroom experiences of the students.

STUDY 3: IMPLICATIONS OF A REPRESENTATIONAL PERSPECTIVE FOR ASSESSMENT OF SCIENCE LEARNING

Background, Rationale

As noted by many researchers, and summarized by Osborne and Dillon (2008), current constrained assessment practices in school science often entail rote memorization in an information transfer model that fails to (a) measure the depth of student learning, (b) provide useful feedback to learners, and (c) match the richness of experiences and representational challenges faced by learners in the classroom, and by scientists in research teams. In supporting science education reform, Duschl (2008a, p. 278) argued that students should participate in "the social processes and contexts that shape how knowledge is communicated, represented, argued, and debated", where activities and tasks "make the students' thinking visible". However, the question of effective formative assessment practices that address directly the adequacy and development of students' representational choices remains under-researched. Hattie and Timperley (2007) and Black and Wiliam (2009), in their recent analyses of effective formative assessment processes, claimed various types of activities, such as sharing success criteria with students, classroom questioning, teachers' written feedback on student work, peer- and self-assessment by students, and formative use of summative tests, enhance subsequent student test performance. However, these prescriptions also tend to ignore addressing representational challenges students face in learning science concepts.

From previous studies we have identified various pedagogical principles that promote an effective focus on student-generated representations for learning in science (Carolan, Prain & Waldrip, 2008; Prain, Tytler, Waldrip & Hubber, 2009; Hubber, Tyler & Haslam, 2010). These principles suggest that teachers and students need to understand representational conventions and purposes and to assess their clarity and adequacy as evidence of students' emerging thinking, reasoning processes, and conceptual understanding. By implication, formative feedback from students and teachers needs to focus on timely judgments and guidance about processes or strategies for understanding representational tasks, redress misunderstandings, confusions, ambiguities and omissions. Formative feedback should also lead to strategies that enable students to self-regulate their next attempt at representation, or integrate multiple representations to show conceptual understanding.

Drawing on this literature, we aimed in this study to: (1) identify formative assessment processes in a science classroom where the teacher focused explicitly on student-generated representations, (2) identify changes, if any, in students' performance in summative topic testing after experiencing a representation-rich learning environment, and (3) consider the implications of these findings for current theory and practice in formative and summative assessment in learning science.

Methods

Our mixed methods research approach entailed collection and analysis of quantitative and qualitative data using case studies of two Year 8 secondary Australian science classes of like quality in terms of students' past performance in science, over a period of six months. Topics covered included nutrition, chemical equations, astronomy, particle theory and air pressure, and force. Students in each class participated in diverse interpretations and constructions of representations of science concepts and processes. These included group and whole class talk about different aspects of the topic, interpreting teacher notes and diagrams, re-representing three-dimensional practical activities in two-dimensional formats, making sense of and re-representing video and other resources used to supplement classroom activities, participating in virtual web-based experiments using tables and graphs, and student construction of their own two-dimensional representations of practical investigations. Data sampling and analysis included observation and videotaping of the teachers' classes, analysis of classroom interactions, teacher and student interviews, examples of students' work, and analyses of students' examination scripts. Scripts were analyzed in terms of students' use of appropriate scientific vocabulary, complexity of sentences in scripts, text readability, number of representational modes used by students in relation to quality of text, and the extent to which modes were integrated through explicit textual ties or embedding.

Results

Analyses of the teachers' focus in formative assessment processes indicated a shift from assessing the correctness of responses to interpreting their thinking as evident in their representational decisions, revisions, and queries. The teachers no longer assumed that students understood representational conventions or had relevant prior conceptual understanding, but focused on interpreting their accounts of their representations and their reasoning as it became apparent from how they represented and coordinated their emerging ideas. The teachers increasingly focused on assessing students' knowledge in terms of their capacity to construct, coordinate and judge the adequacy of their representations in terms of their fit for purpose and persuasiveness.

The teachers diagnostically established students' initial understanding of the concepts of motion, and in subsequent lessons they used formative techniques to explore what was the current state of student understanding and to prompt students to explore alternative perspectives, largely through the use of appropriate questions and judicious use of activities to promote new thinking. This process was influenced by (a) prior understanding of the need to build a coherent account that links properties/behaviour of objects with plausible claims, (b) prior experience with science class methods and the need for accurate measurement of change as the basis for hypothesizing, (c) informal qualitative reasoning around patterns of observed phenomena, and (d) everyday language use of technical terms of topic and everyday ontological accounts of causality. This re-representation work also drew on perceptual contextual clues, as student attempted to identify key observed aspects of phenomena for investigation, as well as problems/gaps/inconsistencies, and also evaluated the adequacy of their own views compared to what they observed with other groups.

The teachers noted that the focus on representational adequacy had the following effects on their formative assessment practices: (1) their feedback and student discussion were more specific and focused on particular features of the representations. (2) teacher and student feedback focused on the precise meaning (or meanings) as well as limitations of meaning entailed in different representational choices, and (3) they focused far more on students' intentions and questions than in past approaches.

Analyses of the students' topic test performance across a range of topics identified the following patterns:

1. Students' scripts provided more detailed responses than was customary. These responses contained more use of appropriate scientific vocabulary, more words, and the concepts were written about at a higher level of readability.
2. Students were more likely to use diverse representational modes, and to incorporate effective textual ties, such as arrows, captions and labeling to link modes. Students were more likely to realize, in subsequent interviews, the limitation of their representation as a complete answer.
3. During interviews, some students explained that their representations allowed them to show properties and understandings that were difficult to verbalize, and that this use allowed them to communicate key ideas more easily.
4. Students were still partly bound by examination expectations, in that they perceived that teachers gave more weight to written responses than to other representational modes.

Conclusions/ Implications

The literature on formative assessment largely draws on cognitive approaches to learning as individualistic information processing, tending to ignore semiotic theories of disciplinary meaning-making, epistemic theories of how science knowledge is produced and validated, and socio-cultural theories of learning through group processes. Our study suggests that a focus on student representational challenges, informed by these perspectives, can provide a practical and valuable focus for formative and summative assessment in this subject. However, our study further suggests that teachers need considerable professional learning support to change to the orientation and strategies proposed in this paper.

Summary of findings

The first paper, '*Learning science through representational generation/negotiation'*, explores the development of a pedagogy based on student generation and negotiation of representations. Based on work over a number of years, with a small number of teachers and key science topics, four key principles of this pedagogy are described and student and teacher data is used to establish the quality of the learning and the issues for teacher change in adopting such a pedagogy. Peirce's (1931-58), triadic model of meaning making is used to explore the role of representation in learning.

The second paper, '*Using organising purposes to support semiotic resource use in school science'*, uses Dewey's notion of 'ends in view' to explore how the immediate, proximate purposes of science activities might be made continuous with more abstracted, ultimate goals of science learning. A practical epistemological analysis of two classroom sequences was undertaken, drawing on the ideas of Dewey (1931-97) and others to show how both students and the teacher used semiotic resources based on more proximate purposes, but how one teacher made these continuous to ultimate purposes. The paper explores how we might create continuity between these different levels of purpose in science lessons.

The third paper, '*Implications of a representational perspective for assessment of science learning*', critiques current perspectives on formative assessment from a representational, pragmatist perspective. It uses case studies of teachers working with lower secondary school students to examine the implications of a representation-intensive pedagogy for both formative and summative assessment, and shows how such a focus can result in more complex student responses on tests, and improved learning. The implications for assessment of this representation-intensive pedagogy are explored.

Overall Conclusions and Implications

In this symposium the practical implications of a pragmatist, semiotic perspective on learning is explored in relation to the development of a coherent pedagogy, to the nature of quality learning, to aligning resources to create continuity between proximate and ultimate purposes, and to conceptualizing and enacting improved assessment practices. Across these explorations, which are grounded in video capture studies of real classrooms, the symposium aims to signal ways forward for school science that bring together the epistemic practices of the discipline itself and the learning needs of students. In this, we see the symposium as an important contribution in helping us move beyond traditional ways of looking at science learning and knowing, to offer a coherent account of broader socio-cultural perspectives on learning.

Discussant: Richard Duschl, Penn State University, USA

Learning science via engagement in epistemic practices has become a very promising line of research. Significant evidence suggests that engaging pupils in growth-of-knowledge practices such as argumentation, modeling and representation promotes important discourse and reasoning opportunities that facilitate 1) students' conceptual learning and 2) teachers' adaptive instruction decision making to guide assessments for learning. Further, when the learning goals build and refine knowledge claims employing arguments, models, and representations, important critique and communication criteria come to the fore. Listening to and examining the talk, models, mechanisms, drawings and visualization help make children's thinking visible; to themselves, to peers and for purposes of teacher' instruction-assisted learning. The Australian research program where lessons are infused with copious use of representations with subsequent links to literacy practices is clearly demonstrating a positive impact on science learning and instruction. The application and connections of didactics and curriculum theory by Anna Maj Johanesson and Per-Olf Wickman to help frame the learning progressions basis of the research does so in important and effective ways. In pushing the agenda, I offer up six challenges to the symposium participants and the broader ESERA research community.

Challenge 1. Extending & Scaling Research in Language & Representation on Learning

There is a need to consider the communication of ideas and information to learners as well as the coherent sequencing of curriculum and instruction aligned to assessments. A review of the language and labels adopted by researchers reveals a wide almost disturbing use of terms and phases. The first challenge is to establish a common language among researchers where the ambiguity of meanings is minimized. Consider a current sample of associated terms and phrases common among scholarly publications:

1) Curriculum Units as: Learning Progressions, Teaching Sequences, Teaching Experiments, Learning Trajectories, Immersion Units, Inquiry Units, Lessons, Activities;

2) Intertwined Epistemic Products as: Evidence=Models=Theories= Explanations

3) Labels for Learning progressions, such as Lower to Upper Anchors; Proximate to Ultimate Purposes, Intermediate Levels, Messy Middle, Construct Map Levels, Meta-representations, Benchmarks, and

4) Terms for Scientific Products/ Practices, such as Modeling, Drawings, Data modeling, Representations, Inscriptions, Visualizations**.**

Challenge 2. Extending & Scaling Research in Cognitive & Social Psychology

Various perspectives compete on learning. The divide is between scholars who maintain extreme positions regarding *cognitive (information processing)* and *situative (sociocultural constructivism)* learning theory perspectives, eschewing the middle ground (c.f., Duffy & Tobias, 2010). The field needs some agreement on models of learning that recognize humans as individual cognitive agents functioning within social networks. Among the set of papers presented in this symposium, there are tensions regarding meanings of learning. Since the mid-1990s research has shown that effective learning environments are based on the following cognitive (CP) and social psychology (SP) precepts (Glaser, 1995):

Structured Knowledge (CP) Instruction should develop conceptual structures to support inference & reasoning;

Prior Knowledge (CP) Learner intuition is a source of cognitive ability that supports & promotes new learning;

Metacognition (CP) Reflection on learning, meaning making & reasoning strategies provides learners a sense of agency;

Procedural Knowledge in Meaningful Contexts (CP) Learning information should be connected with its use;

Social participation and cognition (SP) Social display of cognitive competence via group dialog helps individuals acquire knowledge and skill;

Holistic Situation for Learning (SP) Competence is best developed through cognitive apprenticeship within larger task contexts; and

Make Thinking Overt (SP) Design situations in which the thinking of the learner is made apparent and overt to the teacher and to students.

Might we not agree to these or similar foundational precepts and then show how representations and other discourse practices can aid learners to build and refine models and explanations. Where students' work samples are used as assessments to guide learning and policy decisions, the research and policy communities need to come to agreement on viable models of learning (Gitomer & Duschl, 2007).

Challenge 3. Extending/Scaling Research on Coherence & Resonance in Assessment

Student representations during instruction can provide 'making thinking visible' opportunities that teachers can use to guide decisions for adaptive instruction. The established 'accountability' agenda of measuring achievement with high stakes tests competes with newer 'classroom assessments' agenda of evaluating learning for purposes of guiding/adapting instruction to advance learning. The research on using representations is presently focused on 'Assessment for Learning'. To address the coherence problem, the research needs to also study the use of representation in the 'Assessment of Learning' as well as the delayed and immediate logistics of using representations for 'Assessments for Learning' with external and internal audiences.

Challenge 4. Extending & Scaling the Research into Instructional Practices

A long and strong tradition in science education research has focused on conceptual change. Children's thinking is surprisingly sophisticated in some domains, mirroring adults' ideas, although lack of key conceptual details have been variously labeled misconceptions, alternative conceptions, and naive conceptions. However, children also have sound intuitions from which productive foundational platforms of learning can arise (Duschl, Schweingruber, Shouse, 2007). The key to conceptual change learning is establishing a coherent sequence of learning accompanied by an alignment of Curriculum–Instruction–Assessment. A recommendation from the research synthesis report *Taking Science to School* (Duschl, Schweingruber, Shouse, 2007) is to coordinate instruction around learning progressions that, in turn, focus on core science ideas and scientific practices. Tytler and colleagues have begun to make this important transition in the research programme (one I strongly endorse) as seen in their partial list of teaching principles to enact representation use.

Challenge 5. Extending & Scaling the Research in Data Modeling

The symposium papers emphasize the role representations have on concept learning. An important component of science learning no doubt but insufficient if left unconnected to the evidence used to establish the explanatory claims. The current focus is to pursue the goal of 'using knowledge' in building and refining models and explanations. Thus, developing scientific practices across the grade span is paramount to learning, communicating and evaluating science knowledge claims. An underrepresented focus in both mathematics and science education is data modeling and the accompanying roles of data, chance, and inference. (Lehrer & Kim, 2009) Mathematizing nature is a central dynamic of science inquiry but an oft-underrepresented part of instruction in science education. The message is that instructional time needs to be given over to students' engagement in such refined practices as inventing, constructing, and refining 1) measures, 2) units of measures, 3) representations of measurements, 4) models of chance events, and 5) inferences regarding future data gathering and modeling.

In our research (Lehrer & Schauble, 2004; Lehrer, Schauble & Lucas, 2008) we are finding that instruction must involved learners' with:

(1) Prolonged experience with phenomena,

(2) Posing and revising questions – working over time to make explicit and refine criteria for good questions,

(3) Parsing objects and events into attributes that bear on the question,

(4) Considering/debating means of measuring attributes in ways that support an initial model of the phenomenon (considering the measure properties of those attributes,

(5) Generating/creating data (observing its measure qualities, reliability, etc.

(6) Structuring data (patterns are made, not found),

(7) Interpreting data as evidence – model construction,

(8) Model testing against the original phenomenon & new cases,

(9) Generation/entertainment of alternative models,

(10) Evaluation of model fit, and

(11) Model selection/revision.

The point is that most of the above steps involve types of representations that go well beyond the concept focused drawings that currently characterize the research from the symposium papers. Measurement and data modeling must be central components in science representations precisely because they are central to claims of evidence and explanation.

Challenge 6. Extending/Scaling Research on Attainment of Communities of Practice

A focus of my research beginning with Project SEPIA (Duschl & Gitomer, 1997) and extending to research on argumentation (Duschl & Osborne, 2002) and on inquiry (Duschl & Grandy, 2008) has been the design of learning environments that establish epistemic learning communities (Duschl, 2008; Duschl & Jimenez Aleixandre, 2012). The research on the use of representations in science learning found in this symposium's papers make important contributions to understanding the design of learning environments. However, much more work needs to be done on the whys to engage children in the production and teachers in the assessment of various contexts for making thinking visible; e.g., drawings, models, mechanisms, stories, explanations, establishing criteria, measurements, data modeling, evaluating chance, and drawing inferences.

Mathematics in Physics: Analysis of students' difficulties

Olaf Uhden[1] and Gesche Pospiech[1]
[1]Chair of Didactics of Physics, Technische Universität Dresden

Abstract: The deep interrelation between physics and mathematics is an important fact to understand the success of physical science. Therefore it also influences classroom teaching which leads to additional problems due to mathematical difficulties and knowledge transfer. The teaching and learning of physical concepts seems to be hindered or even neglected. But could not mathematics be used supportively for a physical understanding? In order to approach this question it is important to carefully analyse the difficulties students experience while dealing with mathematics in a physical context. With this aim we observed 15 to 16-year old students from different schools of higher education. They worked at an interactive whiteboard on special physical-mathematical tasks which were designed in order to address the translation process between math and physics. Findings suggest that students focus on a technical use of mathematics. Especially understanding the connection between formulas and physical meaning seems to be problematic for most students. Therefore the conceptual meaning of mathematical descriptions in physics should be stressed in classroom teaching.

Keywords: Mathematics in Physics; Mathematization; Technical and structural skills; Mathematical Modeling; Knowledge Transfer

INTRODUCTION

> "Our previous experience justifies the belief that nature is the realization of the most basic mathematical thoughts. […] Experience remains certainly the sole criterion of usefulness of a mathematical structure for physics. But the truly creative principle is in mathematics." (Einstein, 1956, p. 116, our translation)

The quotation by Einstein sheds light on the deep interrelation between mathematics and physics. It is not the technical toolbox mathematics provides but rather the creative aspect producing new insights into physical structures that hints at a deep conceptual relation between both sciences. Under the perspective of discussions about the importance of "Nature of Science" for science teaching (Lederman, 1992), the conceptual entanglement between mathematics and physics should also have consequences for the teaching and learning of physics. The way theoretical physicists use mathematics, i.e. for modeling and investigating physical behavior, is also an important aspect of the nature of physics.

The importance of taking care of mathematical problems in physics education is also supported by research findings related to knowledge transfer. Generally it can be stated that transfer does not succeed to the desired extent, since knowledge and understanding is acquired context-specific (Brown, 1989). That implies that also the transfer of mathematical knowledge into physics domain can not be expected to happen automatically. On the contrary, it can be suspected that transfer form mathematics to physics is an especially difficult case as there are large differences in the use of and approach to mathematics by physicists. The use of mathematical language in physics differs in many ways from its use in mathematics (Redish, 2005).

On the other hand, the problems and difficulties arising with the use of mathematics within physics education must not be ignored. The objection that the application of formulas and calculations would hinder an understanding of physical concepts, lead to routine and "senseless" computing activities and brings additional mathematical difficulties with it, has to be taken seriously. However, one can assume that these problems stem in large part on the way in which mathematics is involved in physics teaching. Already Richard Skemp, a pioneer in mathematics education research, pointed out the difference between instrumental and relational understanding (Skemp, 1976). By focusing on instrumental skills like rote manipulations and learning rules, it is not possible to achieve a deep (relational) understanding of mathematical concepts. But especially for knowledge transfer a relational understanding is indispensable. Therefore, it is particularly important in physics classes to stress this kind of understanding of the relationship between physical behavior and mathematics.

THEORETICAL FRAMEWORK

A deep analysis of the role of mathematics in physics leads to the distinction into a technical and a structural role. Whereas the technical role describes the tool-like use of mathematics (e.g. calculating numbers), the structural role represents the close connection between physics and mathematics and their structural entanglement (e.g. the possibility to predict new physics from mathematical equations). In classroom situations the technical skills seem to be dominant, although the structural skills – e.g. mathematizing and interpreting – allow a meaningful use of mathematics. Moreover, a focus on the structural role of mathematics would be more in line with the nature of physics than the current instrumental use of mathematics (for a deep investigation of this issue and the derivation of a corresponding didactical model, see Uhden, Karam, Pietrocola & Pospiech, 2011).

A shift in the teaching practice towards the structural skills, and thereby towards the translation between physics and mathematics, requires the consideration of relevant didactic concepts. With the translation to and from mathematics the so called "Grundvorstellungen" (vom Hofe, 1992) – a theoretical concept used in mathematics education research to describe the translation between ideas or meaning and mathematical operations – emerge as they mediate between the mathematical and physical world. The term "Grundvorstellungen" might be best translated as "basic ideas" or "mental models". It refers to mathematical objects (i.e. mathematical operations, symbols etc.) and the ideas and conceptions connected to them. For example, a basic idea of "addition" can be understood as a sum of contributions, i.e. the operation of adding two amounts to get the whole amount as a result. On the other hand, one can think of "addition" as changing an initial state to a final state – as it is the case for describing changes in temperature. Obviously there is not only one correct basic idea of a mathematical operation. Rather it is important to activate the basic idea corresponding to the specific problem one deals with. Therefore one needs to have more than one basic idea available for activation. Enabling a flexible use requires experience and knowledge based on comprehension or, in other words, a relational understanding.

In the physical context these "Grundvorstellungen" have to be connected to an understanding of the physical concepts and be activated in accordance to the physical situation. Sherin (2001) investigated the meanings college students assign to formulas and classified them as so called "symbolic forms". A symbolic form is an entity in a formula which is associated with a corresponding physical behavior, e.g. a fraction stroke with a variable in the denominator means that the resulting behavior is inversely proportional to this variable. But as it is the case with the "Grundvorstellungen", there also exist more symbolic forms for one formal structure. Sherin claims for ongoing research in the same direction with students at a younger age (i.e. high school and secondary school) and for teaching strategies which strengthen the use of symbolic forms. Also an in-depth analysis of its interplay with students' strategies and difficulties is still owing.

RESEARCH DESIGN

The delineated argumentation leads to the main research question which needs to be answered by a qualitative study: What kind of difficulties do students have with mathematical reasoning in physics?

For animating the students to use structural skills and for investigating the resulting difficulties students experience thereby, we developed special mathematical physics tasks in order to address different aspects of translating between physics and mathematics. By working with these tasks the students are challenged to actively carry out the translation and to establish the connection between mathematics and physics not on a calculational but on a meaningful basis. More specifically the tasks contain amongst other aspects

- the creation of a formula on the basis of physical reasoning
- the interpretation of the special cases of a formula
- to draw conclusions based on a formula for physical behavior
- explaining the meaning of a formula

The theoretical assumptions about the nature of the connection between physics and mathematics, as exposed in the model by Uhden et al. (2011), guided the construction of the tasks. The degree of difficulty was validated by the observations made in the pilot study which also gave hints for improvements and additional ideas. The physical topic is mechanics due to the fact that this is the topic with the highest degree of mathematics involved in secondary school.

In total 30 students from different schools of higher education in Germany (“Gymnasium”) were invited to work on the tasks. The students are from class level 9 and 10 – i.e. 15 to 16-years old – and their school grades indicate a selection of mainly good students, but with more satisfactory grades than very good ones.

As the students worked in pairs at an interactive whiteboard we were able to conduct the observation without a video camera because the whiteboard provides the possibility to record the speech and writings simultaneously. The students were requested to discuss the problems with each other and get a joint solution in order to animate them to speak aloud and express their ideas and thoughts. This makes it possible to follow their lines of reasoning and thought processes to some degree. The recorded speech was transcribed and placed in relation to the writings. The transcripts were then evaluated according to the framework of qualitative content analysis (Mayring, 2008).

RESULTS

The observed difficulties were categorized along 4 main categories (which were each divided into subcategories):

- Mathematical understanding
- Superficial translation
- Connection between formula and meaning
- Interference with intuitive notions

The category “Mathematical understanding” refers to pure mathematical difficulties where no explicit connection to physics can be observed. That can pertain to problems with mathematical reasoning or to the already mentioned basic ideas. Nevertheless, these kind of difficulties have influences on the physical argumentation: If an increase in the denominator

leads to an increase of the whole fraction, the interpreted physical behavior will also be wrong.
The category "Superficial translation" is related to a strategic aspect. The established subcategories indicate that the connection between physics and mathematics is guided by superficial criteria. For example, for many students the association of formulas and units seems to be based on rote learning and the formula v=s/t is used once velocity is mentioned, no matter what physical circumstances are present.
The "Connection between formula and meaning" is an essential category that is in close correspondence to the mentioned symbolic forms (Sherin, 2001). The classified difficulties demonstrate a severe lack of understanding of equations and its related physical meaning. For example, the role of physical magnitudes as being a function, parameter, variable or constant seems to be confused or disregarded by some students. That led to discussing the influence of a function on a parameter with the result of confusion.
The category "Interference with intuitive notions" includes that students reject an actually successful connection between physical and mathematical argumentation due to implications that are in contradiction to their intuitive notions. If, for instance, the physical description is not understood as an idealization, the (idealized) mathematical results are considered as unrealistic, leading to a shortened interpretation of the results.

IMPLICATIONS

The outlined difficulties are a plea for a change from the technical to the structural mathematical skills in physics teaching and learning. Especially the observed superficial translation seems to be cultivated by a focus on a technical use of mathematics. And also the mathematical understanding can be assisted by teaching structural skills without delegating this task to mathematics education.
Furthermore, the categorized difficulties with the translation between formula and physical meaning offer the possibility to be addressed explicitly in the classroom in consistence with the symbolic forms. That could help building the foundations for a meaningful use of mathematics in physics teaching. Tasks that address the connection between physics and mathematics, as well as a general qualitatively oriented use of mathematical structures, are further possibilities to stress and support the understanding of structural skills.

PUPILS' VIEWS ABOUT EXPERIMENTS IN SCIENCE

NATURE OF SCIENCE TAUGHT WELL-DIMENSIONED, AUTHENTICALLY, EXPLICITLY AND REFLEXIVELY IN PHYSICS INSTRUCTIONS

Stefan Uhlmann[1] and Burkhard Priemer[1]
[1]Ruhr-University Bochum, Germany

Abstract: Young peoples' views about experiments in research and education have rarely been addressed in science education research despite the fact that experimental work is a main scientific method. The study presented in this article therefore focuses on this problem and assesses students' believes about experiments and investigates the effectiveness of an explicit instruction that teaches both, physics and nature of science (NoS) content. In a "pre-post-follow-up-design", more than 200 pupils aged between 16 and 18 years participated in an empirical exploratory study at the Ruhr-University Bochum, Germany. The results show that young people hold a variety of inadequate and only some adequate views about experimental work. Further, it is possible to change pupils' views about NoS in one-day-interventions as long as the NoS focus is well-dimensioned and an explicit topic of reflexive discussions.

Keywords: nature of science, views about experiments, views about scientists, explicit instructions, scientific inquiry

INTRODUCTION AND THEORETICAL BACKGROUND

Pupils' and students' views about the construct "nature of science" (NoS) are a well-known issue in science education (review e.g. in Lederman 2007). The results of research allow the conclusion that pupils' views about the NoS are more or less inadequate concerning different NoS-aspects such as the role of scientists, the epistemological status of knowledge aso. However, young peoples' beliefs about experiments in research and education have rarely been addressed despite the fact that experimental work is a main scientific method.

Besides assessing students' views about NoS, an important question is, how effective students' views changing instructions should be designed. Studies allow the conclusion that adequate beliefs about NoS cannot be conveyed without being made an explicit topic of discussion (Höttecke 2001, Lederman 2006). Further, to be able to change pupils' beliefs, the educational objectives have to be well-dimensioned. This essentially means that "only" parts of the huge NoS-field – as well as of the physics field – can be made a topic of discussion (Uhlmann & Priemer 2009). Finally, NoS- independent research in education shows the importance of authenticity and reflexivity (Siegel 1989) in instructions.

Both, the need to investigate pupils' views about experimental work in science as well as fruitful ways of discussing the role of experiments with students, led to the following research interest.

RESEARCH QUESTIONS

Which views concerning scientific experiments in research institutions in contrast to experiments carried out at schools do students aged between 16 and 18 have, and how do their views change if they take part in a well-dimensioned, authentic, explicit and reflexive project addressing aspects of the Nature of Science?

DESIGN OF THE STUDY

The design of the NoS-project

In order to address NoS in school instructions, a six hours science project with two focuses for pupils has been implemented. One focus lies on plasma physics, more precisely on the physics of plasma spheres and on the spectroscopy of the contained gases. The other focus lies on the epistemological status of experimental work, e.g. the differences of experiments carried out at schools and, in contrast to this, scientific experiments. The organigram in figure 1 shows further categories discussed in this project.
Apart from experimenting by themselves, pupils also actively communicate with scientific faculty members in interviews about physics content and about various ways of gaining knowledge (Uhlmann & Priemer 2011). They furthermore get the possibility to observe, discuss and learn more about real scientific experiments in laboratory tours.

figure 1 NoS categories

The design of the empirical investigation

In a "pre-post-follow-up-design", more than 200 pupils aged between 16 and 18 years participated in an empirical exploratory study at the Ruhr-University Bochum, Germany. To measure their views about the nature of experiments as well as their views about scientists, a paper-pencil-test had been developed and was now used: BoFEx (Uhlmann & Priemer 2011). Furthermore, a sub-dimension of the VASS (Views About Science Survey, Halloun 2001) was used for triangulation. Several control-variables, such as "content knowledge in general" and "content knowledge in plasma physics" were gathered with additional instruments. The follow-up-test took place three months after the project. The results were evaluated by using the standard tools for descriptive statistics.

RESULTS

A) Students had adequate beliefs about the role of experiments concerning different aspects. For instance, the pupils did not believe in the myth about the "lonely scientist" even before the project had started. The participants knew that scientists organize themselves in "scientific communities" to be able to work more effectively. Adequate views also occurred in the answers to socio-cultural questions. Here, the majority of the pupils for example believed that the development of scientific experiments was independent from the country the scientist lives in, the language he speaks, the religion he believes in etc. Moreover, an above-average amount of pupils stated that even scientists doubted their experimental results.
The participants' views concerning most aspects were, however, rather inadequate. The duration of scientific experiments, for instance, was evaluated in a too unreflected way. Common durations, known from typical school experiments, for instance, of 45 minutes, were often mentioned. Before the project, the participants obviously did not differentiate between "typical" experiments at school and scientific experiments. Apart from that, the pupils seemed to predominantly think that experiments always referred to hypotheses, pure explorative phases were rather unknown. Furthermore and in conformity with other surveys (e.g. Aikenhead 1987; Driver, Leach, Millar & Scott 1996; Edmondson & Novak 1993), evidence of naive realistic beliefs was found. The majority of the pupils for example believed that experiments were able to unveil the truth about nature and that scientific experiments are able to prove a theory. In addition to this, some participants also showed an inconsistent answering behavior concerning some parts of the topic. The pupils were, on the one hand, aware of the fact that even in scientific experiments measurement errors could occur, but they, on the other hand, also thought that one could avoid measurement errors if one only measured accurately enough.

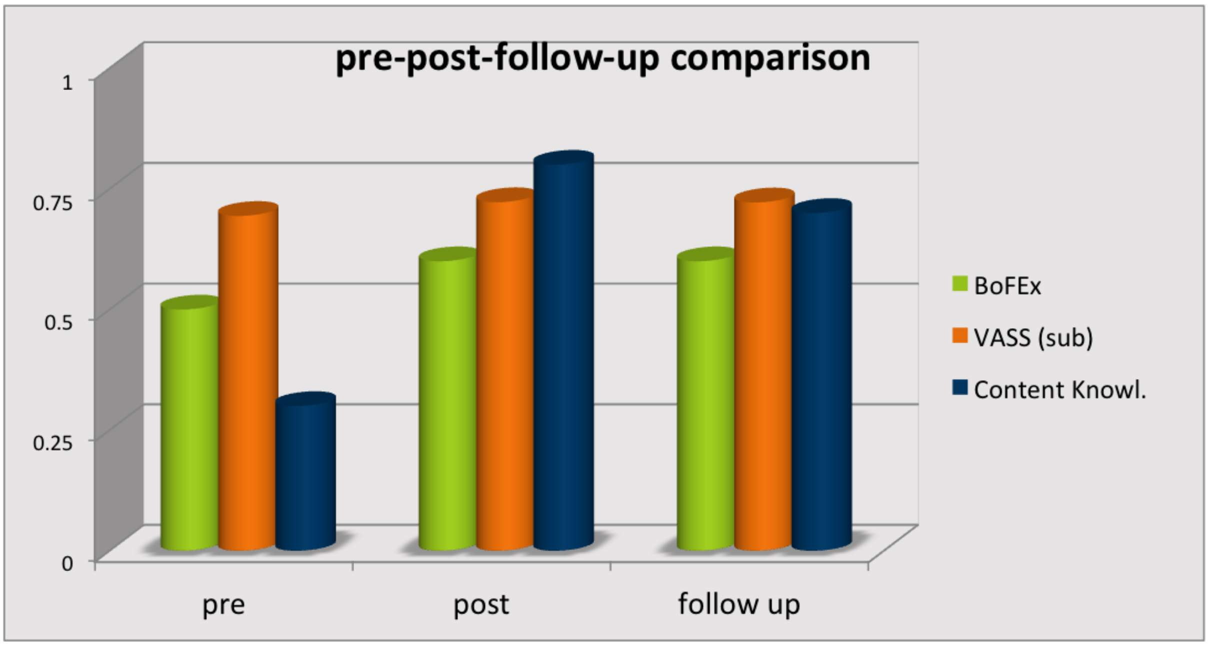

Figure 2: Results of a pre-post-follow-up comparison (BoFEx: views about experiments; VASS: Views about Science Survey; Content Knowl: Content Knowledge Test about Plasma Physics)

B) The comparison of the sum-scores revealed the following results: On the one hand, there is a significant change between the pre- and the post-test concerning the BoFEx as well as the VASS-test. On the other hand, the difference between the post- and the follow-up-test, in both the BoFEx and the VASS, is not significant (see fig. 2).
Hence, the results show that it is possible to change pupils' views about experiments in relatively short interventions.
At the same time, the students significantly increased their knowledge in physics (fig. 2). Even though the drop between post- and follow-up is significant, students in the long run leave the project with a higher level of physics knowledge in comparison to the beginning of the instruction.

CONCLUSION AND IMPLICATION

The results show that students' views about experiments are in some aspects inadequate. Hence, there is a need to develop instructions that teach adequate views of the very basic method of scientific work. The project at hand shows one way. Another aim of the presented approach was showing that it is possible to change pupils' views about the NoS concerning a special focus (beliefs about the "nature of experiments") in a one-day project. In our opinion, a relatively small NoS focus, authentic aspects, reflexive discussions and the integration of both, physics and NoS, are very important. We also believe that different NoS aspects require different methods. Therefore, the interviews with scientists and the guided laboratory tours, which are part of this project, are not a necessary prerequisite of teaching other NoS topics. One could also try, for example, to achieve authenticity by using (historical) original sources such as articles or videos of physicists. This is especially important for schools lacking the possibility of visiting scientific research facilities. The project is meant as a first step. Next steps will be transferring this attempt to instructions in schools by developing more projects with different NoS-aspects and evaluating the efficiency of authentic, explicit, reflexive and well-dimensioned NoS-projects at schools. From our point of view, making different NoS-aspects a frequent explicit topic of discussion can lead to more adequate epistemological beliefs in the long run.

STUDENTS IDEAS ABOUT DIAGRAMS OF A FLOWER AND A PLANT CELL

Unsal Umdu Topsakal[1] *and John Oversby*[2]

[1]Asst. Prof. Dr., Yıldız Technical University, Faculty of Education, Department of Elementary Science Education, 34220 Istanbul, Turkey
[2]Dr., Institute of Education, University of Reading, Earley, RG6 1HY, Reading, UK

Abstract: In this study, primary school students ideas about flower and plant cell in the method of drawing in combination with interviews are examined. The data gathered from 40 students from UK and 16 students from Turkey in year 7. Semi-structured interviews were carried out with 5 students. The students for interview were randomly selected from the total sample. The data was collected in three steps. First the students were asked to draw diagrams of a flower and a plant cell and to Show the parts of them by using labels. In second step a survey consisting of 10 open-ended questions was prepared and given to the students. In the third step, semi-structured interviews were carried out in order to examine the thoughts of the students on this subject more thoroughly. Each students interview lasted for approximately
30 minutes. The data was collected in the school year 2009-2010. Data was treated by qualitative data analyisis method- open coding. The data obtained from the survey and interviews were categorized and arranged based on the alternative ideas of the students. In our study we found that they were simply copying internet diagrams or book diagrams instead of drawing their own diagrams.

Keywords: Diagram, science, flower, plant cell.

INTRODUCTION

Generally pictures and diagrams constitute a very effective, plentiful, and inexpensive teaching medium. Although many studies demonstrate large learning gains when instruction includes diagrams (e.g. Mayer and Anderson, 1992; Mayer, Moreno, Boire, and Vagge, 1999), using diagrams does not always lead to improved outcomes. Relevance may be difficult to determine prior to assessment (Davenport, Klahr and Koedinger, 2007). Pictures have enormous potential as teaching tools. However, they have to be carefully selected and professionally utilized.

Where drawings have been used to probe understanding in science, they have been used in a variety of ways. In a previous study (McNair and Stein, 2001), fifth, eighth and eleventh grade students were asked to draw a plant and include plant parts, functions and information about what plants need to grow in their drawing. Reiss and Tunnicliffe (2001), Reiss, Tunnicliffe and Andersen (2002), and Prokop and Fancovicová (2006) used children's drawings to provide a reliable indication of what children know about the human body (as cited in Köse, 2008, p. 283). Tunnicliffe and Reiss (2000) have conducted studies that investigated children's conceptions about plants. They conducted interviews with 36 children, ages 9-14, recording their comments and reasoning. The results indicated that, as children age, their reasons for grouping plants become more complex: in addition to relying on shared anatomical and habitat features, they begin to show evidence of a knowledge of taxonomy and use this knowledge to group plants (as cited in Goins, 2004, p. 2).

In this study, students' ideas about flowers and plant cells using the method of drawing in combination with interviews are examined.

METHODS

Design of the Research

A qualitative approach was adopted. The interviews were semi-structured.

Universe and Sampling

The data was gathered from 40 students from UK and 16 students from Turkey, all in year 7. The research was performed in Reading (UK) and Sakarya (Turkey). Semi-structured interviews were carried out with 5 students. The students were randomly selected from the total sample.

Instrumentation and Analysis

The data was collected in three steps. Firstly, the students were asked to draw diagrams of a typical flower and a typical plant cell and to show the parts of them by using labels. In the second step, a survey instrument consisting of 10 open-ended questions was given to the students. In the third step, semi-structured interviews were carried out. The data was collected in the school year 2009-2010. The data was treated by qualitative data analysis (open coding) (Bryman and Burgess, 2004).

RESULTS

All the students drew a simple flower, not a complex flower such as a daisy. This indicated that the students may not know the identity of the flower that they drew.

The Open-Ended Questions

Question 1. Which flower do you believe you drew?
The daisy was found to be the main flower they believed they drew.
Question 2. Do you think all the flowers have same scientific section? Please explain
24/40 students from UK and 13/16 students from Turkey mentioned that all the flowers have the same scientific section. None of them could explain this.
Question 3. Is there any other scientific section of a flower that you know about? Please give an example and explain what the differences are.
Most of the students mentioned that they did not know any other scientific diagram.
Question 4. Why did you choose to draw this scientific diagram?
For the students, 'I like it' was found to be the main reason (12) for choosing to draw these diagrams.
Question 5. Please draw a scientific diagram of a daisy.
All of the students from UK and Turkey tried to draw a diagram of a daisy but all of them were incorrect.
Question 6. Which kind of plant cell did you draw?

The palisade cell was found to be the most common answer of the students from UK (11/40).
The tulip cell was found the most common answer of the students from Turkey (8/16).
Question 8. Do you think all the plant cells are same? What other kinds do you know?
Half of the students said that all plant cells are same. The other half who wrote that all plants cells were not same could not explain it correctly.
Question 9. Why did you choose to draw this plant cell?
The most mentioned reason was that, "it was the only one I know" (14).
Question 10. Is the cell in Fig. 1 plant cell or an animal cell? Why do you think so?
Please show the parts of this cell by using labels.

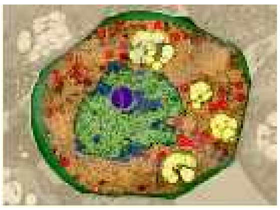

Figure 1. Image of a cell accompanying open-ended question no. 10

17/40 students from UK and 13/16 students from Turkey mentioned that the cell was an animal cell. Most said that it was because it is round.

The Interview

All the students interviewed (5) thought that all flowers have the same scientific diagrams and they did not know about complex flowers. They thought that all plant cells were same. They did not know any other plant cell diagram. Also all of them mentioned that the illustrated cell was an animal cell because it was circular.

DISCUSSION

There are many surveys that show that students who used integrated (diagram-based with text) explanations are better able to understand concepts (e.g. Butcher, 2006; Davenport et. al., 2007). In our study we found that the students could not draw diagrams, they can only copy them from those given. We saw that most of the students interpreted visuals as the same and also wrongly that is, they probably did not know how to read the diagrams.

Although diagrams are considered as effective personal tools for solving problems, applied research in education has identified diagrams are a widespread problem: and that students lack spontaneity in diagram use (Uesaka and Manalo, 2007). Most of the biology books include more words than diagrams. So, it may be that the teachers and students try to learn biology subjects mainly from the text, not from the diagrams. In addition, in examinations the students are asked to use diagrams instead of making diagams, for example they are asked to label diagrams. So this makes students focus on given diagrams.

IMPLICATIONS

Whether diagram-making or diagram interpretation should be part of the science curriculum is an important issue. This is the usual tension of learning basic facts (a low level content rich curriculum that is very traditional) or of learning scientific procedures, such as diagrammaking and interpretation. This matter needs to be explored among science educators and policy makers, as a development of this research.

USING KITCHEN STORIES AS STARTING POINT FOR CHEMICAL INSTRUCTION IN HIGH SCHOOL

Jenni Vartiainen[1], Maija Aksela[2], Anu Hopia[3]
[1]Helsinki University
[2]Helsinki University
[3]University of Turku

Abstract: New approaches to chemical instruction are needed. High-school students do not find chemistry and chemistry education interesting, and there is a correlation between attitude and learning results. Therefore, novel approaches to chemistry instruction that the student can relate to need to be designed. Molecular gastronomy and so-called kitchen stories are one possible context to be used as the starting point for chemical instruction. This study is part of a larger design research, the aim of which is to study the use of kitchen stories in context-based chemistry teaching. The purpose of this case study is to find out how kitchen stories can be used as the starting point for chemical instruction on high school level, taking the aims of Finnish National Curriculum into consideration. The studied kitchen stories were collected from high school students by 20 teachers, who participate in 3-year in-service training Molecular Gastronomy in Chemistry Teaching. The stories were analysed by grounded content analysis. Four groups emerged from the data: (1) Proverbs and folktales, (2) Methods and ingredients in cooking, (3) Nutrition and health, and (4) Cleaning and restoring. Group number 2 is relevant for the present study. The central chemistry contents were identified according to Finnish National Curriculum, and the stories in group number 2 were classified according to these contents. Out of the twenty-two contents from the curriculum, six can be covered with kitchen stories. On the second phase of the design research, teaching models based on kitchen stories will be developed to cover these contents in chemistry instruction. Also the effects on students, when using kitchen stories as the starting point, will be studied.

Keywords: Kitchen stories, curriculum, chemical instruction

BACKGROUND

On a global scale, the youth see the importance of natural sciences to the society, but do not consider these subjects important on a personal level. In addition, the level of interest towards studying natural sciences is low (OECD, 2010). Finding the answer for the lack of interest is one of the biggest challenges in science education today (Lavonen et. *al*, 2009). The lack of interest and too few applicants to science education is a challenge also in Finland. Finnish high-school students are among the highest performing in science in the OECD countries (OECD, 2010). However, Finnish high school students' attitudes towards science are more negative than in any other OECD country (Hautamäki et. *al*, 2007). The interest is particularly low towards chemical phenomena (Lavonen et *al*. 2005). There is a demand for new meaningful approaches and perspectives for chemical instruction.

There are many challenges in chemistry education. One of those is the lack of relevance. In their everyday life students do not see any reason why they should learn chemistry, and where the knowledge in chemistry is needed. By approaching chemical facts and phenomena through meaningful concepts from everyday life, some challenges in chemical education can be addressed (Gilbert, 2006). Context-based approach to chemistry education is one way to look at chemistry using concepts and applications as starting points for the development of scientific ideas (Bennet et *al*., 2006).

Based on many previous studies, context-based approach to learning can be used to improve the students' interest and attitude towards chemistry education (Pilot & Boulte, 2006). However, there is relatively little evidence that context-based learning could improve learning results (Bennett, 2005). According to a research by Jager and Weld (1999), there are significant differences in learning results between context- and concept-based learning. According to Gilbert (2011), learning can be enhanced if the learner is interested in the context and sees the significance of the learning experience.

There are six features that should be present in high-quality chemistry education: 1) the conceptual structure of chemistry, 2) the process of chemistry, 3) the technological manifestations of chemistry, 4) chemistry as a "personally relevant" subject, 5) the cultural aspects of chemistry, 6) the societal implications of chemistry (Kempa, 1983). By using molecular gastronomy and kitchen stories as the starting point for context-based teaching of chemical concepts, all these features can be included in a way that interests the student through every-day experience (Västinsalo & Aksela, 2010).

MOLECULAR GASTRONOMY AND KITCHEN STORIES

Molecular gastronomy is a relatively new scientific activity, looking for mechanisms of phenomena occurring during cooking and in culinary transformations (This, 2009). One perspective to molecular gastronomy is to observe and analyse scientifically the so-called kitchen stories. Kitchen stories refer to culinary advice that has been passed along from generation to generation of chefs, mothers, and cookbooks. Over 20,000 kitchen stories have been collected from French cookbooks. In molecular gastronomy the scientific study of kitchen stories is one key element (This, 2005). Thus, kitchen stories may function as a fertile starting point for chemistry education. The stories can be regarded as scientific claims with more or less open inquiry.

OBJECTIVES

This study is part of a larger design-research (Edelson, 2002), the aim of which is study how to approach chemical education through kitchen stories from many perspectives. The most important perspectives include: 1) learning chemical concepts through kitchen stories, 2) developing the students' argumentation skills, 3) developing the students' thinking through kitchen stories and inquiry-based learning, 4) supporting the students' interest towards chemistry by context-based approach to kitchen stories, 5) developing practical teaching models that the teachers participating in the 3-year in-service training use with their students.

Design research is a cyclical process, in which design and research are done during theoretical and empirical phases. Design research can be divided into three phases: 1) problem analysis, 2) design process, and 3) design solution. These phases are cyclical and repeated several times (Edelson, 2002).

This design research is conducted during the three years while Molecular Gastronomy for Chemistry Teaching in-service training for chemistry and home economics teachers is being developed. 20 teachers from 10 schools, one chemistry and one home economics teacher from each school, participate in the training. The training includes 12 2-day sessions, and new approaches to chemical concepts through kitchen stories are being developed for each session. In between the sessions, the teachers test the new approaches in practice and revise them according to the educational needs of their students. The teachers report their experiences and practices systematically. The reports are being used in the evaluation and development of the process.

Molecular Gastronomy in Chemistry Teaching in-service training has been designed to fulfil the requirements of context-based learning: setting of focal events, behavioural environment, specific language, and extra-situational background knowledge (Gilbert et al, 2011). The teachers' active role in the development of context-based teaching model is important. They need to be provided with materials and pedagogical interventions, so that the context can be implemented in the teaching (Hofstein & Kesner, 2006).

This case study is part of the problem analysis of the larger design research, the aim of which is to pin down the needs and define the goals of the design research.

OBJECTIVES OF THIS PROBLEM ANALYSIS CASE-STUDY

The aim is to map, how chemistry education can be approached through kitchen stories, taking the aims of National Curriculum into consideration (OPH, 2004). In a previous problem analysis case study, the students' needs for new approaches to chemical instruction were studied and the students' interest towards the context of molecular gastronomy in education was scrutinised (Västinsalo & Aksela, 2010).

This research was guided by question:

1. From the perspective of Finnish National Curriculum, how can kitchen stories be used as the starting point for chemical instruction at high school level?

METHODS

The research data was gathered by in-service teachers, who had enrolled for Molecular Gastronomy in Chemistry Teaching training, before the first session. The in-service teachers were asked to gather kitchen stories from high school students. The concept of kitchen story was clarified to the teachers through written examples and they were asked to explain the concept to their students as well before gathering the stories.

All the kitchen stories that the teachers gathered were included in the research data. After the similar stories had been erased from the data, there were altogether 126 different stories. The stories were analysed by content analysis, and classified according to grounded theory (Cohen et al., 2009). Four different classes emerged from the data. The classes were formed as follows: All stories that included word play (rhymes etc.) or were clearly proverbs were tagged with number 1. For example kitchen story "cold coffee makes you beautiful" is a Finnish proverb. The stories that included some kind of an advice or instruction for cooking were tagged with number 2. For example story “Kiwi fruit prevents gelatine from gelling” was tagged with number 2. Number 3 was used to mark all stories that gave advice on how to benefit health or beauty with food. For example, story “blueberries improve eyesight” was tagged with number 3. All stories that included advice to use food ingredients in cleaning, instructions on how to take care of cooking instruments, or advice on how to restore food were tagged with number 4. For example, stories “do not wash cast iron pan with dish soap” and “never freeze once frozen food again” were tagged with number 4.

The classes that rose from the data were named accordingly: (1) Proverbs and folktales, (2) Methods and ingredients in cooking, (3) Nutrition and health, and (4) Cleaning and restoring. From these classes, number 2 is relevant for the present study.

In the next phase, the central chemical contents were identified from the Finnish National Curriculum. The number of different contents was 22. The kitchen stories from class 2 (Methods and ingredients in cooking) were categorised under these contents.

The main chemical phenomenon of each story was defined in the story. For example, “you cannot boil eggs on top of Mount Everest (boiling point of water)”. After the main chemical phenomenon of all stories from class 2 had been defined, the phenomena was categorised according to chemical contents in the National Curriculum. In this case, the boiling point is a property of water and belongs to category: Water and its properties. A second example: “Eggs stored in room temperature whip better (denaturation of proteins)” was categorised under Proteins.

To improve the reliability of classification, it was done several times by the researcher. Also another researcher did the classification and a kappa value was counted to measure of inter-rater agreement (Brennan & Prediger 1981).

RESULTS

The group Methods and ingredients in cooking (n=65) was divided further into classes that rose from the Finnish National Curriculum (OPH, 2004). All chemical contents from the chemistry curriculum for high school were collected. There were 22 main contents. The kitchen stories were classified according to the curriculum contents by the main chemical phenomenon that occurs in the story. Examples of stories are in table 1. The measured inter-rater agreement was 90%. Free marginal kappa value (Randolph, 2005) was 0,88.

Table 1 Examples of kitchen stories

Chemical content from curriculum	Example of kitchen story	n=
Carbohydrates	“Brown sugar will soften, if you place a piece of dark bread next to it.”	11
Atmospheric substances	“If you want to leaven a cake with yeast, set it in a warm place.” ”If you use soda in baking, add buttermilk.”	6
Lipids	“If you want low-fat soup, you can absorb fat from the surface with an ice cube.” “If you add oil in cooking water, pasta won’t get entangled.”	6
Oxidation of organic compounds	“Wine will not ferment in a dirty bowl.” “Dip pieces of apple in orange juice and they won’t get brown in salad.”	4
Proteins	“Eggs will not foam, if they are fresh.” ”Salt in soup will make the meat cook slower.”	24
Water and its properties	“Add salt to boiling water, the potatoes will cook faster.” “You can prevent the ingredient from going sour by adding baking soda.”	14

CONCLUSIONS

From the perspective of Finnish National Curriculum, kitchen stories are a possible way of approaching chemical concepts in teaching. There are six themes out of 22 in the Finnish Curriculum in which kitchen stories can be utilized: Water and its properties, Atmospheric substances, Oxidation of organic compounds, Carbohydrates, Proteins, and Lipids. In France, molecular gastronomy has already been used to cover contents of the curriculum at comprehensive school level (This, 2005). The kitchen stories can be handled as scientific claims.

In previous studies on context-based learning, there has been a need to alter the contents in the curriculum (Millar & Osborne, 2000). Based on the results from this study, there is no need to change the contents of curriculum to use molecular gastronomy and kitchen stories in chemistry teaching as the method can be easily integrated into the existing curricula.

Teaching models based on kitchen stories will be developed in the design research according to this problem analysis. These models will include contents that increase the students’ interest and methods that the students’ themselves wish would be more frequently used in instruction. The models will include reading literature, laboratory work with traditional and modern equipment, ICT-based learning, sensory experiments, and social, student-centred methods (Lavonen et *al*, 2005; Juuti et *al*, 2009).

The results from the previous problem analysis of this design research show that the students are interested in the kitchen story approach (Västinsalo & Aksela, 2010). There is a correlation between attitude and learning results: Those who have a positive attitude towards chemistry get better results (Salta & Tzougraki, 2004, Freedman, 1997). However, there is only little research evidence on whether context-based learning can improve learning results (Bennett, 2005). According to this problem analysis case study, the following goals can be set for the design research:

- Developing teaching models based on kitchen stories that cover the following chemical contents in the Finnish National Curriculum: Water and its properties, Gases, Oxidation of organic compounds, Carbohydrates, Proteins, and Lipids
- Studying the functionality of the developed teaching models through the teachers participating in Molecular Gastronomy in Chemistry Teaching in-service training and developing the models further.
- Studying the effects of these teaching models on concept learning as well as argumentation and thinking skills in students.
- Gathering more kitchen stories and studying how they can be used in teaching of chemical concepts.

The next case study will be to research concept learning, argumentation and thinking skills among high school students in the context of kitchen stories.

THE USE OF THOUGHT EXPERIMENTS IN TEACHING PHYSICS. THE CASE OF THE PRINCIPLE OF EQUIVALENCE

Athanasios Velentzas[1] and Krystallia Halkia[1]

[1]University of Athens

Abstract: In this work an attempt is made to explore the possible value of using thought experiments in teaching physics to upper secondary education students. Specifically, a qualitative study is designed to investigate the extent to which the thought experiment "Einstein's elevator", by drawing material from books that popularise physics theories, can function as a tool in teaching the "principle of equivalence". It was shown that the teacher of physics by using this thought experiment may help students mentally arrive at situations that considerably exceed their everyday experience. In this way, students are able to approach physics theories with a high level of abstraction. Students after the experimental implementation were able to formulate the "principle of equivalence", explain phenomena based on this principle and also explain the deflection of light in gravitational fields as a consequence of this principle.

Keywords: Thought Experiments, Secondary Education, Principle of Equivalence

BACKGROUND, FRAMEWORK, PURPOSE, AND RATIONALE

In science, apart from real experiments, thought experiments (TEs) are extensively used (Mach 1896/1976). TEs are experiments that are "performed in the laboratory of the mind" and distinguished scientists such us Galileo, Newton, Einstein and Heisenberg used TEs in their works (Brown 1991, Sorensen 1992). Also, a number of philosophers of science (e.g. Mach 1896/1976, Kuhn 1977, and Popper 1959/1999) have analyzed the role of TEs in science.

TEs, besides the significant role they play in physics, could be proved important educational tools too. Indeed, TEs are an integral part of physics textbooks, whose authors use TEs in order to present physics theories to students (Velentzas et al. 2007). Also, the use of TEs in the classroom motivates students to use their imagination, develop their critical thinking, make hypotheses and infer outcomes (Matthews 1994, Reiner & Gilbert 2000). In addition, teachers consider that TEs are important tools in teaching physics laws with abstract and concise formulations (e.g. theory of relativity), because they feel that TEs help in bridging the gap between students' experience and the concepts to be taught (Helm et al. 1985).

On the other hand, well known scientists (e.g. Einstein, Gamow, and Landau) used TEs in order to communicate physics theories to the public. They wrote books that popularise physics theories wherein a lot of TEs can be found, especially when the authors present physics theories of the 20th century (Velentzas et. al. 2007). The code of science popularization (which is a non formal science code) appears to be very appealing to students (Halkia & Mantzouridis 2005).

In the present work an attempt is made to explore the possible value of using TEs in teaching physics to upper secondary education students. Specifically, a qualitative study is designed to investigate the extent to which the TE "Einstein's elevator", by drawing material from books that popularise physics theories, can function as a tool in teaching the "principle of equivalence". Especially, the research question of this study is: To what extent does the use of the TE "Einstein's Elevator" may help students formulate the "principle of equivalence", explain phenomena based on this principle and explain the deflection of light in the gravitational fields as a consequence of the principle.

METHODS

The TE known as "Einstein's elevator" was selected, in a popularized form as it was found in Einstein's two books (Einstein 1961, Einstein & Infeld 1938). The study of the relevant literature was used to design a lesson plan. A pilot study took place in a sample of 8 students divided in two groups. This study helped us to detect students' difficulties and weaknesses of the lesson plan and design the final form of it.

The lesson plan was carried out through semi-structured interviews. The teacher acted both as an interviewer and as teacher, according to the "teaching experiment" method (Komorek & Duit 2004). The teacher was responsible for supporting the interaction among the students and he intervened when the student-student interaction was no longer fruitful.

The sample of the research consisted of 40 upper secondary school students (aged 16, grade 11) from 6 different schools in the area of Athens. The students were divided into 11 groups of 3-4 students each. The experimental implementation lasted 2 hours for each group of students.

The data were collected by taping and transcribing the interviews, and by distributing a questionnaire to students 15 days later. This questionnaire included open-ended questions. Methods of qualitative research were applied to analyse the data (Erickson 1998).

THE TEACHING / INTERVIEW PLAN

1st step: Students, discussing their experience in a vertically accelerating booth, (e.g. in an amusement park), reach the conclusion that the upward (or downward) acceleration "adds" (or "subtracts") an amount of gravity. Then, they create in their mind an environment with "weightless conditions" inside a booth which is in a free fall.

2nd step: Students, imagining a uniformly accelerating booth out of any gravitational field (GF), develop relevant syllogisms and reach the conclusion that phenomena occurring in the accelerating booth are the same as if the booth were motionless in a homogeneous GF. Then, with the help of Einstein's relevant text they generalize the results and formulate the "principle of equivalence".

3rd step: Students apply the "principle of equivalence" when a spaceship is accelerated out of any field of gravity to different directions and they discuss the meaning of what is "upward" or "downward".

4th step: Students taking into consideration the "principle of equivalence" and imagining a light beam inside the accelerating booth are led to conclude that a beam of light is deflected by the action of a GF. They apply this in the case of a light beam passing near the Sun.

FINDINGS - RESULTS

(i) Students managed (starting from their own experience with gradual abstractions) to mentally arrive at situations that do not take place in everyday life.

Specifically, discussion motivated by students' experience of fast elevators or amusement parks played a significant role in the development of the TE. All students described or agreed in describing an experience that the upward acceleration is as if "it adds an amount of gravity" whereas the downward acceleration is as if "it subtracts an amount of gravity" and finally they arrived at the conclusion that inside a booth which falls freely "it is as if there were no gravity". Then, by using the TE students reached the conclusion that the acceleration outside a GF "imitates gravity". As a matter of fact, most students (32/40) mentally eliminated the effect of the GF in the space of an accelerating booth and were able to predict that a man inside the booth "can stand upright". The rest of the students (8/40), at first, were hesitant or claimed that the man "suspends", but they overcame this difficulty with the help of their classmates who basically argued that "the man is outside the GF and because of the inertia he tends to move with a constant velocity and therefore the floor of the accelerating booth pushes him". After that, all students were able to predict the "fall" of the objects in the booth with the same acceleration. At the end of the process students claimed that the passenger of the booth in the TE "feels as if the booth is stationary on the Earth".

(ii) The process of performing the TE and then the reading of Einstein's corresponding text seemed to have helped students so that they may formulate in their own words the "principle of equivalence" (e.g. "instead of considering an accelerating booth outside a GF, you can consider it stationary within a GF").

However, it is worth noting that approximately half of the students, while they predicted correctly the phenomena in an accelerated system outside a GF, yet for the explanation they did not use the term "principle of equivalence". These students preferred to describe the phenomena according to the inertial observer; a fact which relates to their persisting idea that only the external observer knows the "absolute truth".

(iii) While students' everyday experience may play a positive role in the "performance" of a TE, it may however be an obstacle when the consequences of a TE considerably exceed the experience of students.

Indeed, whereas in the beginning the experience in the amusement park seemed to play a beneficial role in the development of the TE, later on, in one of the applications where the result was in obvious opposition to the everyday experience (a drawing where a spaceship accelerated "horizontally") seemed to be an obstacle for a number of students. This obstacle was overcome through the discussion and finally they arrived at the conclusion that the meaning of "upward – downward" relates to the direction of the equivalent GF.

(iv) Students by using the TE reached the conclusion that the light is deflected by the action of a GF as a consequence of the "principle of equivalence".

All students claimed during the "performance" of the TE that the light beam is deflected to a direction opposite to the acceleration. However, there was a difficulty for many students (25/40) to explain the shape (curve) of the "path" of light, but they understood it once it was explained by their classmates or by their teacher. Then, students in their discussion to respond to a relevant question decided that the passenger of the booth will ascribe the deflection of light beam to the action of a GF. Also, students were in a position to apply qualitatively (with the appropriate drawing) the above conclusion to beams of light which pass quite near the Sun.

CONCLUSIONS AND IMPLICATIONS

In the present work an attempt is made to use a TE as a didactical tool for teaching physics. It resulted, that this TE, as it is presented in Einstein's books "popularizing" physics, may constitute useful educational material for designing lesson plans to teach the "principle of equivalence". This is due to the fact that in the TE there is the element of narration and the handling of lesser mathematical formalism so that students may easily follow the lesson plan with interest focusing on the meaning of concepts. This facilitates the process of a basic understanding, something which must be the aim of teaching physics in secondary education.

It was shown that the teacher of physics by using this TE may help students mentally arrive at situations that considerably exceed their everyday experience. In this way students are able to approach physics theories with a high level of abstraction. Students after the experimental implementation were able to formulate the "principle of equivalence", explain phenomena based on this principle and also explain the "deflection of light in gravitational fields" as a consequence of the principle.

In conclusion, the results of the present work, as well as of the other research (Velentzas & Halkia 2010, Reiner & Burko 2003, Gilbert & Reiner 2000), support the view that TEs constitute important didactic tools for students of upper secondary education in learning principles and laws of physics with a high level of abstraction.

THE EFFECT OF LESSON DURATION (45 VS. 60 MINUTES) ON QUALITY OF PHYSICS INSTRUCTION

Rainer Wackermann[1] *& Burkhard Priemer*[1]

[1]Ruhr-University Bochum, Germany

Abstract: Although there is no theoretical framework and hardly any empirical investigation on optimal lesson duration, several German upper level secondary schools currently prolong lesson dura- tion from 45 minutes to 60 minutes in order to improve instructional quality. This study inves- tigates this assumed impact of lesson duration for the case of physics instruction. Therefore 60-minute-lessons of four physics teachers are videotaped and analyzed in comparison with 45-minute-lessons of the same physics teachers from a previous study. Video analysis follows the theory of basis models of teaching and learning by Oser (2001). A pupil questionnaire and an expert instructional quality rating accompany the video analysis. This study wants to deliv- er first hints whether the change in lesson duration alone impacts instructional quality or whether additional professional development is needed to make efficient use of the prolonged lessons.

Keywords: Lesson duration, learning processes, basis models, physics instruction

BACKGROUND AND AIMS

The origin of lesson durations is widely based on tradition and pedagogical intuition rather than on learning theories or empirical investigations. In Germany, the lesson duration was changed from 60 down to 45 minutes in the nineteenth century to allow pupils to help in agri- culture in the afternoons (Fölling-Albers, 2008). Although this justification is clearly outdated today, schools continue in this tradition. Other European countries like Switzerland or Finland have similar lesson durations, with physics and sciences in general often taught as “double- lessons” (2x45 minutes). Outside of Europe exist slightly longer lessons in the case of South Korea (50 minutes) or Canada, where lesson duration may vary from school to school. Al- though some work has been done on “learn time” in the broadest sense (see Carroll (1964), Walberg, (1986), Aufschnaiter (2003), Seidel & Shavelson (2007)), at present there is no theoretical or empirical work concerning the optimal duration of lessons.

Recent attempts in Germany to improve instructional quality have let several schools intui- tively decide on 60-minute lessons. This change, again, is not based on learning theories and has not been investigated empirically, yet. It is therefore especially timely now to start inves- tigating the effect of lesson duration on quality of instruction.

Making use of the current transforming situation in some German schools, we formulate the following research aim: Does the recent prolongation of physics lesson duration from 45 up to 60 minutes have an effect on instructional quality? The answer to this question may deliver hints towards the optimal physics/science lesson duration for all European countries.

DESIGN AND METHODS

This study builds on the knowledge base of Wackermann et al. (2010). It makes use of the fact that Wackermann et al. (2010) conducted a professional development program for physics teachers four years ago. The study involved videotaping and was carried out under the condition of traditional 45-minute lessons. By chance, four of the former participating teachers today teach under the condition of 60-minute lessons. Instruments of the former study are applicable to investigate instructional quality and will be used again in this study.

The sample consists of four physics teachers from two German secondary schools that recently changed the lesson duration from 45 to 60 minutes. Each teacher (and one of their classes, 8^{th} to 10^{th} grade, respectively) is videotaped four to five times under both conditions. The teachers were/are asked to present lessons where they introduce something new. Videos were/are taken according to the guidelines of the TIMS-video study (Stigler & Fernandez, 1995). In addition, pupils were/are administered a very short questionnaire right after each videotaped lesson.

Variables under investigation include *basis model orientation* (video analysis), pupils' *ability to follow instruction* (pupils' questionnaire) and certain aspects of instructional quality such as *clarity* or *pacing* (expert's view, video analysis). Basis model video analysis investigates in time-slots of 1 minute whereas the expert rating and the student questionnaire cover the whole lesson. The full set of variables and instruments is listed and explained in Wackermann et al. (2010).

Instrument	Variables	Origin
Basis model video analysis	*Basis model*, *Instructional phase*, Level of implementation (each separate for teachers and pupils)	Oser (2001); Wackermann et al. (2010)
Instructional quality rating	*Clarity and structuredness*, *Cognitive activation*, *Pacin*g (and more variables)	Clausen (2002)
Short pupils' questionnaire	*„I was able to follow the instruction today* "	Wackermann (2010)

The study follows an experimental design with pre- and post-measurement. Pre-videos were taken four years ago (see Wackermann et al., 2010) and post-videos are taken beginning in fall 2010 when lesson duration had been prolonged to 60-minutes for about two years.

Data acquisition is halfway complete and analyses have started. Two of the four teachers have been videotaped four times each under the new condition. For both research questions the planned statistical analyses include $\chi 2$-tests for categorical variables and t-tests for continuous variables, respectively.

One hypothesis concerns the duration of the last instructional phase of a learning process, which deals with important aspects like decontextualization or content linkage. The analysis of 80 videos of 18 different physics teachers (see Wackermann et al., 2010) under the condition 45 minutes showed that not even 3 % of lesson time were spent on this last phase of a learning process. The finding was astounding, since teachers received coaching with respect to organization of learning processes. Since mostly only the last phase of a learning process was missing, a modest prolongation of lesson duration may facilitate completion of learning processes (Borowski, Fischer, Trendel & Wackermann, 2010).

FINDINGS

The basis model video analysis has been carried out for the two teachers and statistical tests for difference show no significant change in *basis model orientation* from 45 to 60 minutes. At this point in the analysis, neither the use of basis models nor the completeness of basis models nor the average level of implementation have altered. Learning processes were not significantly more often complete under the new teaching condition. However, those instructional phases that were carried out appear significantly longer (significant mid-sized effect) under the new condition.

Also at this point in the analysis, the pupils' view on their ability to follow the instruction shows no significant difference between the two teaching conditions. The pupils on average find it rather easy to follow the instruction with natural significant differences within the classes (especially high- vs. low-performer).

The expert instructional quality rating is currently performed. A first glimpse also seems to indicate no significant change in general aspects of instructional quality such as pacing or clarity.

CONCLUSIONS AND IMPLICATIONS

Surprisingly, so far learning processes did not get completed as expected (see hypothesis in Design section). Instead, the first instructional phases appear to be simply prolonged and the teachers fill the whole lesson with much the same content as before. It is therefore not surprising that pupils on average find it rather easy to follow the instruction (although this was already the case for the pre-videos). In conclusion, the two teachers so far investigated seem not, at least not as expected, to make use of the prolonged lessons.

The analyses concerning the effect of lesson duration on general aspects of instructional quality, currently underway, seem to support no significant change in the instruction. Simply altering the outer conditions does not seem to alter teaching behavior. As a result, additional professional development for the teachers seems to be necessary to make efficient use of such prolonged lessons.

This study, especially in view of the sample size, obviously does not allow any kind of generalization. However, it may offer implications as to where future research could point to, possibly extending to other subjects, "double-lessons" or professional development programs. Videotaping of the other two teachers is currently foreseen for fall 2011 with final results being available in spring 2012.

RESEARCHING EXPERIMENTAL PHASES IN CHEMISTRY EDUCATION USING VIDEO ANALYSIS

Maik Walpuski[1] *and Alexandra Schulz*[1]
[1]University of Duisburg-Essen

Abstract: This study focuses on experimentation as a subject-specific operation in chemistry education. Laboratory experiences are said to enhance the students' learning achievement, interest, and motivation. In this paper a study dealing with the effectiveness of different quality criteria of experimental work in classroom situations is described. The study consists of two parts, an observational and a quasi-experimental part. In the first part experiment-specific quality criteria and their influence on interest, motivation and learning outcome are observed in regular chemistry lessons. In the second part teachers are trained based on these categories (e.g. post-processing of the experiment, instructional efficiency, problem-solving) in order to enhance interest, motivation and learning outcome in their classes. Results of this study offer practical implications to enhance the quality of experimentation phases in chemistry lessons.

Keywords: quality, experiments, chemistry education, video analysis

THEORETICAL BACKGROUND

General quality of instruction is defined "*as a bundle of characteristics describing instruction (process quality) which have a positive effect on teaching outcomes (product quality)*" (Einsiedler, 2002). Thus, 'good instruction' can be defined as something from which we can measure positive effects concerning the students´ performance. Reusser and Pauli (2003) describe the quality of instruction in a systemic model (fig. 1).

The systemic model of quality in education is divided into three levels: the system; the school and family; and the class and individuals. All of these levels are subdivided into the quality of learning opportunity and the quality of using the offer, so they all interact.

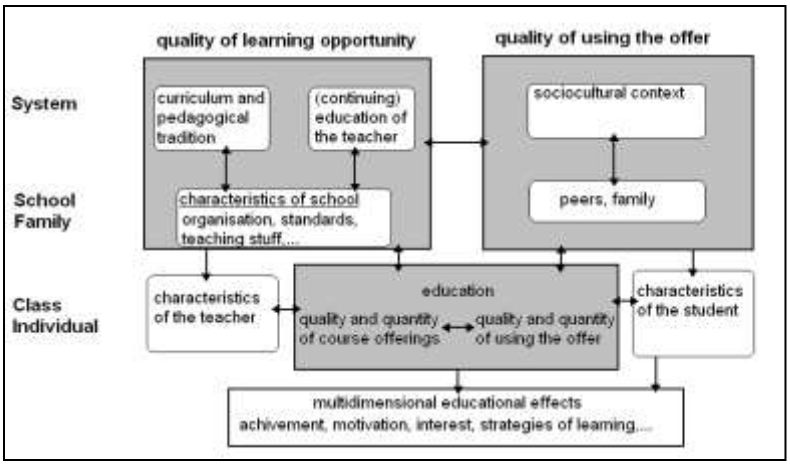

Figure 1: Systemic model of quality in education (Reusser & Pauli, 2003)

Helmke (2003) describes factors of quality in education in an "offer and use model" (fig. 2). In this model, education is deemed to be an offer, whose effectiveness depends on the teacher, the context and the activity of learning (the use). In turn, the use depends on many mediators like the family, the achievement potential and the context.

In this project, we will look at the class/individual level and within this level at the education, the characteristics of the students and the effects of instruction (output).

Most characteristics of instructional quality are for general instruction. Helmke (2002) and Ditton (2000) state that it is "out of date" to look only at the general quality of instruction, so they call for specific characteristics of quality in specific subjects. Rakoczy & Pauli (2006) speak about the "need of subject and domain specific processes to measure subject specific quality in education".

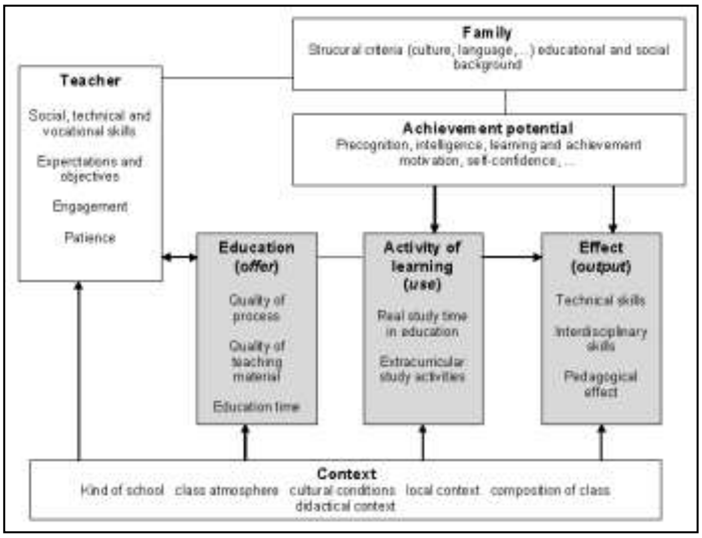

Figure 2: Offer and use model (Helmke, 2003)

Experimentation has a central and distinctive role in chemistry instruction (Hofstein & Lunetta, 1982) and can be seen as such a subject-specific operation (Bader & Schmidkunz, 2002). Results of research on learning from experiments in school are controversial (Hofstein & Mamlok-Naaman, 2007). Some studies criticize laboratory work to be unproductive; others report the possibility of meaningful learning in experimental situations. Most of these studies are conducted under experimental conditions to evaluate only one criterion or some few isolated criteria which enhance students' performance in experimental phases. However, there is a lack of research studies in regular chemistry instruction to identify experimental-specific quality criteria.

RESEARCH QUESTIONS

Based on the theoretical background the aim of the project is to translate the results of the research on general instructional quality to specific characteristics in chemistry education (in particular to the experimental phases) to identify experimental-specific characteristics of quality that enhance the learning process. This is achieved by observational research (video-analysis) based on a category system.

The following research questions are due to the objectives:

- Which general characteristics of instructional quality can be transferred to experimental phases in chemistry education?
- Which requirement of intervention can be derived from observed chemistry lessons?
- Which effect does the intervention have on the achievement, interest and motivation of the students?

METHODS

Procedure

The study consists of two parts. In the first part, regular chemistry lessons have been observed to test first ideas about experimental-specific quality criteria. These ideas were used to develop a video coding system and to plan an intervention study aiming at optimizing the run of the presented lessons. In the second part (intervention study), the teachers were trained by video feedback on the first lesson and asked to teach the same content again in another class, but to optimize the lesson according to the quality criteria. To describe experimental phases in chemistry education, 18 regular lessons with experimental phases have been videotaped in the first part in 2008/2009 (10^{th} grade; mid-school; topic *alcohols*). The teachers (N = 15) were instructed to demonstrate a typical chemistry lesson under the condition that at least one experiment should be conducted. These video-data were analyzed based on a category system. These 15 classes (18 lessons) were the first control-group. One year later (school year 2009/2010), 10 of the 15 teachers were consulted for an intervention in which the characteristics of quality in experimentation phases were given. In addition, data from another direct control group (parallel classes without intervention), were collected previous to the intervention group to make sure that there were no additional influencing factors apart from the planned intervention (e.g. new school books, new facilities etc.).

Instruments

This category system (fig. 3), consisting of a low-inferential and a high-inferential component, has been conducted and evaluated before. It is developed chemistry-specific based on general quality criteria, the systemic model of quality in education and results of research studies on experimentation. The objectivity and reliability was proved by the inter-rater reliability (K: .55-1.0; ICC_{unjust} = 0.82 ($F_{1,220}$ = 23,72; p < .001). The validity was proved by the comparison of extreme groups (high points vs. low points in terms of quality). It could be shown that the group with the high score has a significant higher learning achievement than the group with the low score. So the conditions for an objective, reliable and valid category system are fulfilled.

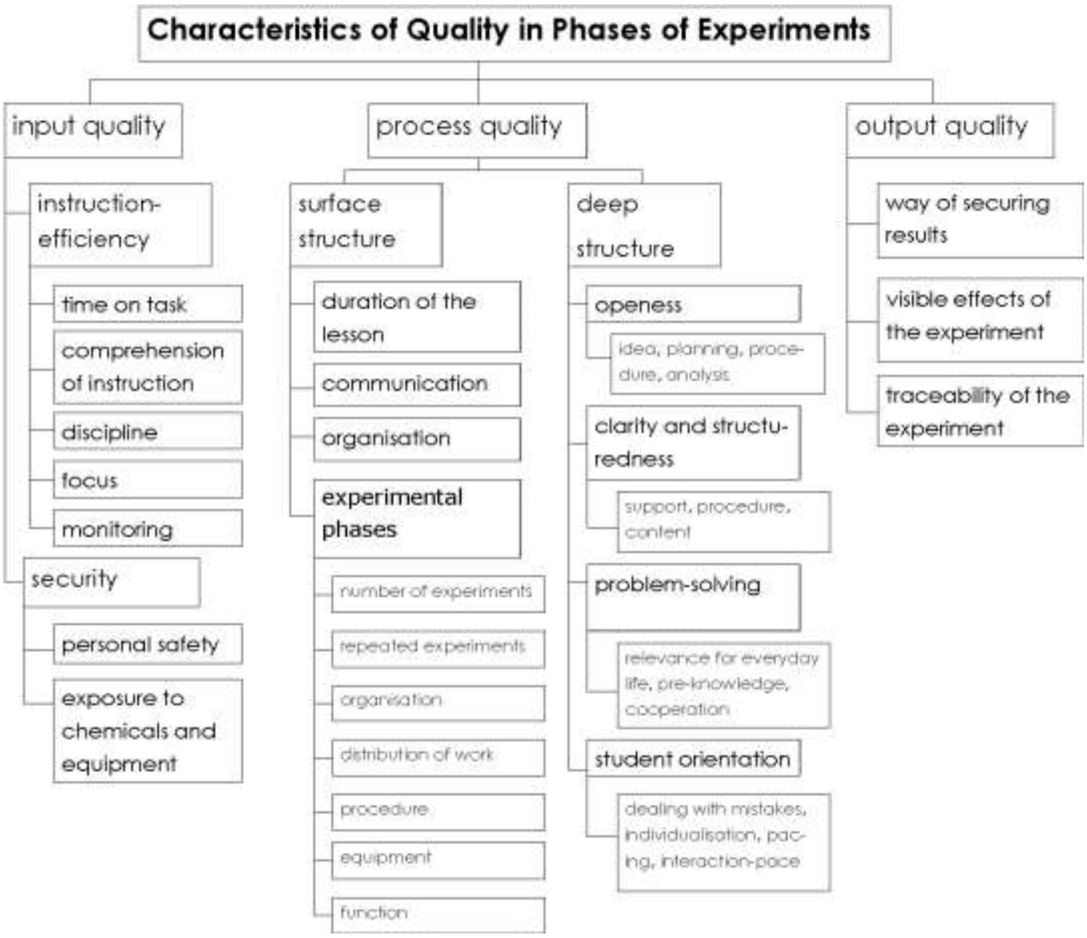

Figure 3: Category system

To be able to explain chemistry instruction and not only to describe it, video-analysis should be completed by using further criteria like interest, motivation, intelligence or capacity (Seidel et al., 2006). To consider this, students' characteristics (learning achievement, motivation, interest) have been acquired in a pre-post test design. Additionally, the cognitive abilities (Heller & Perleth, 2000) and the knowledge of scientific procedures (Klos et al., 2008) have been collected, so the test data could be analyzed more precisely. The second study (intervention study) was conducted one year later (2009/2010). The same teachers as in the first study participated in the intervention study and the same test instruments were used. In the intervention study, the experimental phases were enriched with the possible quality criteria from the first study using a short teacher training. The students of the first study formed the control-group and the students of the second study the intervention group.

RESULTS

From the first data collection, among others, the following criteria with a positive influence on the learning outcome were derived: *amount of students' talk, students' explanations, hypothesis testing, instructional efficiency, problem-solving, traceability of the experiment.*

Using the video training, the teachers were instructed to improve these criteria in their lessons. The results of the second video analysis (intervention study) show that the training was successful. The descriptive comparison of the intervention-group and the control-group (video-analysis) illustrates the increase of quality criteria in the intervention-group. Among others, significant higher values concerning these quality criteria could be shown for the categories *statements of students, hypothesis testing, instructional efficiency, problem-solving* and *traceability of the experiment*. Furthermore, it could be shown that the intervention-group has a higher learning achievement than the control group (t (420) = 3.181; p = .002, d = .31). This result proves the assumption that the selected criteria are useful to improve the quality of chemistry lessons and students' learning. A difference between these groups concerning the motivation and interest of the students could not be found (p > .05) in general, while the situational interest of the intervention-group was significantly higher than the situational interest of the control-group (t (275) = 4.196; p < .001; d = .54). A mediation-analysis was conducted to prove the situational interest as a mediator for the learning achievement. The result of the mediation-analysis showed a partial mediation.

CONCLUSIONS AND IMPLICATIONS

General quality criteria of instruction could be transferred to experimental phases in chemistry education (first study). An improvement of the experimental phases - based on the quality criteria – is attended by an increase in learning achievement and situational interest (second study/intervention). An increase in motivation and general interest could not be shown. One explanation is that motivation and interest are strong constructs (Krapp, 1999) and not to be changed in one lesson. Maybe a longer period of intervention might have an influence on motivation and interest of the students.

[2]Ludwig-Maximilians-University Munich, Germany, girwidz@lmu.de

Abstract: Our study evaluated a context-based unit on carbon dioxide gas sensors. The major goal was to develop a context-based approach. That sought to help students create new knowledge about the key concepts of the operating mode of carbon dioxide gas sensors and transfer their knowledge between different contexts. To this, three issues of learning physics of sensor technology were specially considered.

First, the sensor was used within a context which is expected to be meaningful and relevant to the students. Such the context of poor indoor air quality in classrooms was selected. It should provide an answer to the students' questions: "How does a carbon dioxide gas sensor work?" and "Why should I learn this subject?".

Second, the use of different forms of representation such as texts and pictures should help students to construct an individual multiple mental representation of the content.

Third, workbook-exercises presented in different forms of representations should help learners to apply their knowledge and to get a deeper understanding of the key concepts of the subject matter.

The influence of contexts and exercises on knowledge acquisition and knowledge transfer to new situations was tested by using a pre-, post-, and follow-up design. Data from 170 participants were collected and analyzed by using a MANOVA. The results of the overall MANOVA showed a significant effect of the representation format of exercises on the acquisition of knowledge. Students who did exercises that were presented by a picture-based format performed better on knowledge tests than those who did the same exercises presented by a text-based or mixed format. For the acquisition of declarative knowledge the context was not the crucial factor. However, students who learned within the context 'indoor air quality' performed better on transfer tasks than those who learned without anchoring learning and knowledge to such a context.

Keywords: context-based, sensor technology, exercises, forms of representation

INTRODUCTION

In 1929 the inert knowledge problem was described and coined by A.N. Whitehead (Whitehead, 1929). He used the term 'inert knowledge' when describing the failure of knowledge to transfer to new situations. According to this, inert knowledge is knowledge that can be recalled when people are specifically prompted to remember it. But it cannot be used to solve problems in new situations. There is a gap between the recall of knowledge and the use of knowledge. It is quite possible to acquire knowledge but to be unable to use it. Well, it is a long time ago since Whitehead said this. But today the problem is the same. In 2005 Mandl & Kopp noted that, "Little has changed since A.N. Whitehead wrote this over 75 years ago" (Mandl & Kopp, 2005, p. 15). Six years later Gilbert et al. (2011) discussed five major problems in science and mathematics education. They argued, among other things, that "Students often cannot transfer knowledge to situations other than the one in which it was learned" (Gilbert et al., 2011, p. 817).

The ‘inert knowledge problem’ was analysed by Renkl et al. (1996). They described possible reasons for the acquisition of inert knowledge. Three categories of explanations including some deficits that are expected to influence the acquisition of inert knowledge were discussed by Renkl et al. (1996):

- The first one comprises explanations with respect to deficits in the structure of knowledge. De Jong et al. (1996) distinguish four types of knowledge: situational knowledge, conceptual knowledge, procedural knowledge, and strategic knowledge. The term ‘deficits in the structure of knowledge’ means that the relevant knowledge is not available. Some possible reasons could be that students learned isolated facts, concepts or algorithms. It is also often explained by insufficient conceptual knowledge. In this case, the quality of the conceptual knowledge is inadequate. For example, students can give definitions, and principles about the solution of a problem, but they are not able to give a step by step guide for solving this problem.
- The second point is about the situated nature of all learning. That is to say, knowledge and mental representations are dependent on context. Knowledge is linked to the context in which learning takes place.
- The third point is about the access of knowledge. In this case, the relevant knowledge is available. But it can‘t be used, because of lacking control over their own meta-cognitive processes. For example, students must be motivated to use their skills, their learning strategies and their knowledge. Therefore they must become interested. The relevant skills are not applied or not available.

In summary without additional arrangements students do not have the ability to apply what they have been learned in a new context and the transfer fails.

In the 90s the CTGV (1997) provided examples of learning environments that focused on the idea of overcoming inert knowledge. They used the concept of anchored instruction and designed, among other things, the Jasper series. They assumed that the use of mathematics in authentic contexts supports the students’ reasoning, problem solving, and communication skills (CTGV, 1997). The effectiveness of anchored instruction was evaluated by various researchers. Research on Jasper series suggested that students who receive Jasper problems perform better in problem solving, show less anxiety toward mathematics, are more likely to see mathematics as relevant to everyday life, more likely to see it as useful, and more likely to appreciate complex problems than do students who receive traditional one-step word problems. They also showed that transfer does occur to analogous problems in different contexts (CTGV, 2000). The Jasper series were modified and follow-on projects were developed in the last years. Results of research on these projects (e.g. “Scientist in Action”, “SMART“ …) are presented and discussed by CTGV (1997, 2000). In Germany the group around Kuhn (2010) modified the concept of anchored instruction, too. The essence of their approach is to “anchor” instruction in the context of real newspaper articles. They acknowledged the results of CTGV and evaluated large effect sizes. Kuhn (2010) showed that students who receive the modified anchored instruction concept perform much better on transfer tasks, physics achievement tests, and show higher motivation than do students who receive traditional textbook units.

RATIONAL

In conclusion, we know that there are three main reasons for the acquisition of inert knowledge and we also know that the concept of anchored instruction seems to be useful to overcome these causes. But, the research to date in the field of anchored instruction has tended to focus on one or two causes. It seems necessary that all three causes should be addressed by a general concept. The aims of our project were: ...

- first, to overcome the 'inert knowledge problem'. From this we developed a concept for physics courses that was thought as likely to consider the three causes for the acquisition of 'inert knowledge' and to make students' knowledge useful for other contexts by transfer. For that purposes the content and special workbook-exercises were presented in different forms of representations. Both were positioned within a realistic and authentic context.
- second, to make subject matter more relevant for students. To this, a context-based unit on non-dispersive infrared gas sensors was developed. The subject matter was positioned within an everyday life setting. The context was formed around the main application of these sensors.
- third, to undertake a comparative study to examine the effectiveness and practicality of our concept. Especially the influence of our concept on the acquisition of knowledge, transfer, students' motivation, learning strategies, and estimation of authenticity and relevance with regard to content.

RESEARCH QUESTIONS AND HYPOTHESES

The research questions driving this project were:

- How does the use of our special workbook-exercises (presented in different forms of representations) influence knowledge acquisition and learning activities?
- How does the use of authentic applications of sensors influence transfer of knowledge and motivation?

Corresponding to this, the following hypotheses were tested:

- Students who do exercises that are presented by a text- and picture-based format perform better on knowledge tests than do students who receive exercises that are presented by a picture-based or text-based format.
- Students who work with exercises that are presented by a text- and picture-based format carry out more cognitive activities than do students who receive exercises that are presented by a text-based or picture-based format.
- Learning within authentic applications of sensors leads to better performance on transfer tests than learning without linking knowledge to authentic applications of sensors.
- Learning within authentic applications of sensors leads to higher motivation than learning environments without authentic applications.

METHODS

Sample

170 students (88 females, 80 males; ninth-grade) from three secondary schools, ranging in age from 14 to 15 years, participated in this study. They all came from Baden-Württemberg (southwestern Germany). The students were randomly sampled to experimental and control conditions. Before implementation of a two-week context-based unit on non-dispersive infrared gas sensors the students were not taught the physics or the applications of the sensor. So they had no knowledge of this. The teachers who participated in this study were trained to use the sensor and in applying our concept.

Design

We used a pre-, post-, and follow-up design. We implemented a 3x2 factorial design with format of exercises and application as factors. The factor A "format of exercises" had three levels. The factor B "application" had two levels.

		A: format of representations of exercises		
		picture & text	picture	text
B: application of sensors	authentic	I (n=33)	II (n=29)	III (n=27)
	not authentic	IV (n=27)	V (n=27)	VI (n=27)

Table 1: Design

For example, the first group consisted of 33 students. They received a treatment with exercises that were presented by a picture- and text-based format. And the treatment they got was based on an authentic application of the sensor. All together, we evaluated six treatments, whereof three treatments are used as control groups.

Research Setting and Procedure

We developed a two-week unit on **n**on-**d**ispersive **i**nfra**r**ed gas sensors that contained both the operating mode of the sensor and their application in everyday life.

In its entirety, the two-week unit consisted of four learning steps across four hours. The students received a workbook for all learning steps describing the activities to be performed. The first of the four steps required students to identify the problem of poor indoor air quality. The second learning step highlighted the operating mode of the sensor. Using a workbook, students were introduced to the key components and the functionality of **n**on-**d**ispersive **i**nfra**r**ed gas sensors. In the third step, students worked in groups and collected data to explore the increase of carbon dioxide in classrooms during a lesson. The fourth learning step required students to develop their own personal plan to regulate and control the air conditioning. The experimental and the control treatments were instructed by their physics teacher or by the author for 90 minutes each week.

Data Sources

We used a pre-, post- and follow up – test design to explore students'

- content knowledge,
- transferable knowledge,
- current motivation towards physics,
- learning strategies,
- self-efficacy,
- estimation of authenticity, and
- estimation of relevance with regard to content.

For control we also assessed students' gender, age, and marks in mathematics, German language, and physics. The items of all questionnaires were multiple-choice questions (typically three distracters were offered) or rating scales ranging from 'strongly agree' to 'strongly disagree.

Pre-Test

Students' current motivation towards physics und learning strategies was assessed with a questionnaire contains four standardized tests.

- The *current motivation-scale* was derived from an instrument used and developed by Prenzel et al., (1996). This test instrument having 15 questions contains five subscales: (1) intrinsic motivation, (2) extrinsic motivation, (3) identified motivation, (4) unmotivated, and (5) introjected.

- The l*earning strategies-scale* was derived from an instrument used and developed by Seidel et al. (2005). This test instrument having nine questions contains three subscales: (1) rehearsal, (2) elaboration, and (3) organization.
- The *self-efficacy-scale* was derived from an instrument used and developed by Pekrun (2005). This test instrument having six questions.
- The *estimation-of-authenticity-scale* was derived from an instrument used and developed by Kuhn (2010).
- The *estimation-of-relevance-scale* was derived from an instrument used and developed by Seidel et al. (2005).
- Students' *content knowledg*e was assessed with a questionnaire contains 38 questions and five subscales: (1) voltage, (2) construction of the sensor, (3) operating mode of the sensor, (4) operating mode of thermocouple, and (5) infrared radiation. The test items were developed and tested by the author. An alpha reliability of .71 was found.

Between the two weeks:
After one week, students received a short questionnaire including the following instruments:
- current motivation scale,
- learning strategies scale,
- estimation of authenticity scale, and
- estimation of relevance with regard to content scale

Post- und follow-up-test
Students' transferable knowledge was assessed by a post- and follow-up-test. The questionnaire had 20 questions contains three subscales: (1) construction of a methane-sensor (2) operating mode of a methane – sensor, and (3) increase of carbon dioxide in classrooms and elevators.

Data Analysis
To determine, if there were any statistically differences between the groups on the dependent variables a MANOVA was used.

SELECTION OF SOME RESULTS AND DISCUSSION

Equivalence of pre-test scores
A 2x2x2 MANOVA on pre-test scores indicated no differences between the experimental and control groups (treatment by gender by class).

Results of the Overall MANOVA
The results of the overall MANOVA were statistically significant. Using the Pillai's trace, there was a significant main effect of „format of representation of exercises" and of „authentic applications" on the observed variables ($F_A(8,384)=10{,}741$; $p=.005$; $\eta^2=.074$; $F_B(4, 159)=16{,}949$; $p=.000$; $\eta^2=.101$; $F_{AxB}(8,384)=5{,}899$; $p=.018$; $\eta^2=.041$). The multivariate test 'Pillai's Trace' tests the null hypothesis of equality among the group means for the effect of the factors A and B on the weighted linear combination of the dependent variables. So it represents the proportion of variance in the weighted linear combination of the dependent variables. Thus the larger the value of Pillai's Trace, the greater the difference among the groups on weighted linear combination of the dependent variables.

In the following explanations we limit ourselves to the first research question and hypothesis.

How do the use of our special workbook-exercises (presented in different forms of representations) influence the acquisition of declarative knowledge?
It was hypothesized that participants who do exercises that are presented by a text- and picture-based format perform better on knowledge tests than do students who receive exercises that are presented by a picture-based or text-based format. However, the results of this study did not show that the students who worked with both types of exercises performed better on knowledge tests than the other students.

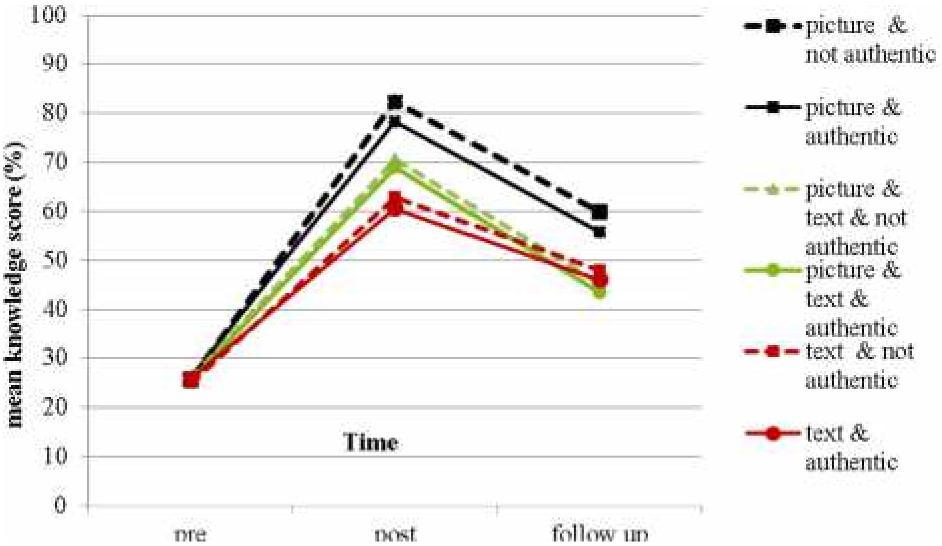

Figure 1: The multiple line chart presents the results of the content knowledge questionnaire among the three measures and the six groups.

The multiple line chart above (see figure 1) shows the mean knowledge score (declarative) of all six groups. All scores are presented in percentage quotation. If a student answers all questions correctly, he or she will get 100% of the points. The declarative knowledge was assessed in the pre- post- and follow-up-test. What we can see from this chart is that students who did exercises that were presented in a picture-based format performed better on knowledge tests than those who did exercises that were presented in the combined format and those who did exercises that were presented in a text-based format.

Discussion
There are several possible explanations for this result. One might be that exercises that are presented in a picture-based format are more attractive for students than exercises that are presented in a text-based format. Another possible explanation is that students who did the exercises that were presented in a picture-based format did their tasks in a short time. So in half an hour, they performed nearly twice the number of exercises than students who did the exercises that were presented in a text-based format. They took a longer time to do their tasks.

How does the use of our special workbook-exercises (presented in different forms of representations) influence learning activities?
It was hypothesized that students who work with exercises that are presented by a text- and picture-based format carry out more cognitive activities than do students who receive exercises that are presented by a text-based or picture-based format. The following multiple line chart (see figure 2) shows the mean learning activity score of the three groups. As you can see from this chart students who did exercises that were presented in a text- and picture based format estimated their cognitive activation as well as students who did the other exercises.

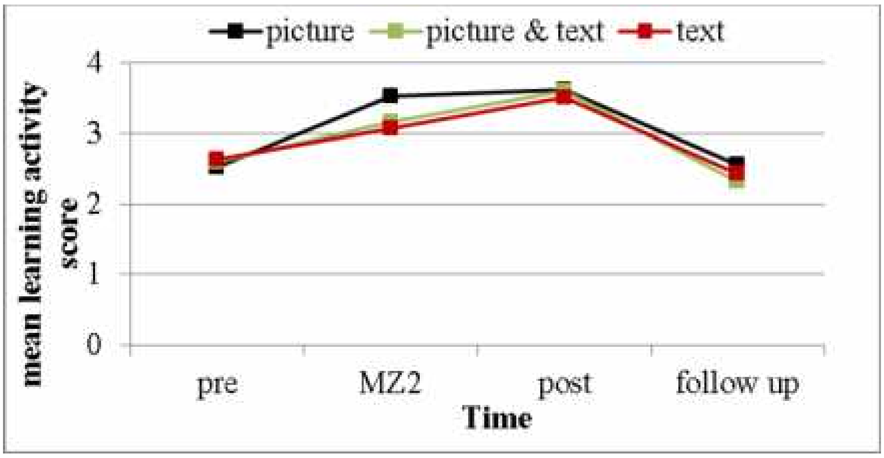

Figure 2: The multiple line chart presents the results of the learning activity questionnaire among the four measures and the three groups.

Discussion

This result may be explained by the fact that it's difficult for students to give a realistic self-evaluation of their cognitive activities and learning strategies. It seems that they tend to an overestimation of their own capabilities. So the data must be interpreted with caution.

Abstract: In this article, the purpose will be argue and discuss dialogics interactions that happen in a science class of basic teaching, and if they had produce means with the prop of a Information Technology and (IT). These interactions will be analyzed under the point of view of an analytic tool (MORTIMER and SCOTT, 2002) with the Bakhtin dialogics forecasting.

Keywords: science class, semiotic mediation, speech genres.

INTRODUCTION

In the lastest years, the Science Teaching has enfatized the Human being as active participant in the context in that lives. The influence is the both directions. Looking at this situation, the focus is on the language. According to Vygotsky (2000) the language is an instrumental activity. So, researches in Sciences Educating with its center in the nature of interactions between teachers and students to build scientific knowledge has grown since the late decade (MACHADO, 1999; MORTIMER, 2000; SUTTON 1997; MARTINS et al, 1999). In this article, the purpose will be argue and discuss dialogics interactions that happen in an science class of basic teaching, and if they had produce means with the prop of a Information Technology(IT). These interactions will be analyzed under the point of view of an analytic tool (MORTIMER, 2002) with the Bakhtin dialogics forecasting.

LEARNING OBJECT AS A METACOGNITIVITY TOOL

This work has an objective to argue and discuss briefly that through interactions between teacher and student. It was possible to aid in the building of meanings about the digestive system in a classroom with the use of an object to approach built with the focus to teaching for improve metacognitive~~-~~tools of students, taking like reference Bakhtin theories. ITs are instruments created by men to act on the nature or the material reality (VYGOTSKY, 1991). Since the last decade studies come indicating that the use of a learning object (LO) can to present~~ate~~ a sociodiscursive built, when this presents a dialogic relations between student and teacher (KOZULIN, 2003; AFFONSO, 2008). In this work interest us is how the Theory of L.S Vygotsky realize this language.

Semiotic Mediation in Vygotsky and the sign for Bakhtin.

To Vygotsky, the language is an instrumental activity and means fundamentally two things:

1 - That it is ever mediated by instruments,

2 - and these instruments are created by men in function of the nature of actions planned by him.

In this way, to Bakhtin, these instruments are signs and then, ideology's products. And, as the ideology has a meaning and it is a part of a reality (natural or social reality) as all physic body. The sign is an instrument of production or a consumption product. But otherwise of them it also reflects and refracts another reality that it is exterior. The existence of sing is nothing more than the materialization of this communication. In this fact is that consist all of nature of ideological sings. But this semiotic area and this continuous paper of social communication as a conditioning factor didn't appears in anyone place more clear and complete than in the language. The word is an ideological phenomenon in excellence (WERTSCH, 1991). It meeting point between Vygotsky and Bakhtin theories is the semiotical mediation. To Vygotsky it's grounded beyond the language, it is in interactivies' situations. These situations become viable the mechanism of internalization, that means, the inner reconstruction of an external operation (VYGOTSKY, 2000).

In this article, the purpose will be argue and discuss dialogic interactions that happen in a science class of basic teaching, and if they had produce means with the prop of an IT. The IT used in this work was the LO, Route food (Figure 1). These interactions will be analyzed under the point of view of an analytic tool (MORTIMER and SCOTT, 2002) with the Bakhtin dialogic forecasting.

Figure 1 – LO's Route food screen

METHODOLGY AND RESULTS' DISCUSS

The presenté analysis in this article it's grounded in the analytical tool of Mortimer and Scott (2002). This tool shows how the kinds of communicative approaching are produced through teachers interventions. Analyzing the actuation form as the teacher done to guide the interactions that aid in the building of meanings in science classroom. The tool is the product of a tentative to develop a writing language do describe the genre of discuss (BAKHTIN, 1986) in the science classrooms. The survey was conducted in a State school with elementary school students from 13 to 14 years. The methodology used in this research was qualitative type, which contain detail data and they are related to people, places and talk, and it demand complex statistic treatment (BOGDAN & BIKLEN, 1994).

Table 1 – Analytical Tool to analyze the interactions and the production of meanings in science class (MORTIMER and SCOTT, 2002).

Analysis aspects	Teachin' phocus	Approaching	Acts
	Teacher' s intents	communicativity approaching	Interation Patterns
	Contents		Searcher's interventions

In this article the emphasis was given in the teacher's intents and in the teacher's interventions. In these aspects were really happen these dialogical interactions between teacher and student. Nevertheless, the contents of LO was teaching focus being elaborated in the wholeness of process of human digest. The communicative approaching occurred through the use of this IT. The approaching having like mainly: the dialogical and the authority- (WERTSCH, 1991).

In these aspects were really happen these dialogical interactions between teacher and student. Nevertheless, the contents of LO was teaching focus being elaborated in the wholeness of process of human digest. The communicative approaching occurred through the use of this IT. The approaching having like mainly: the dialogical and the authority (WERTSCH, 1991).The dialogical approaching happened when students told the trajectory of the feeding contents through the gastric-intestinal handle (Figure 2).

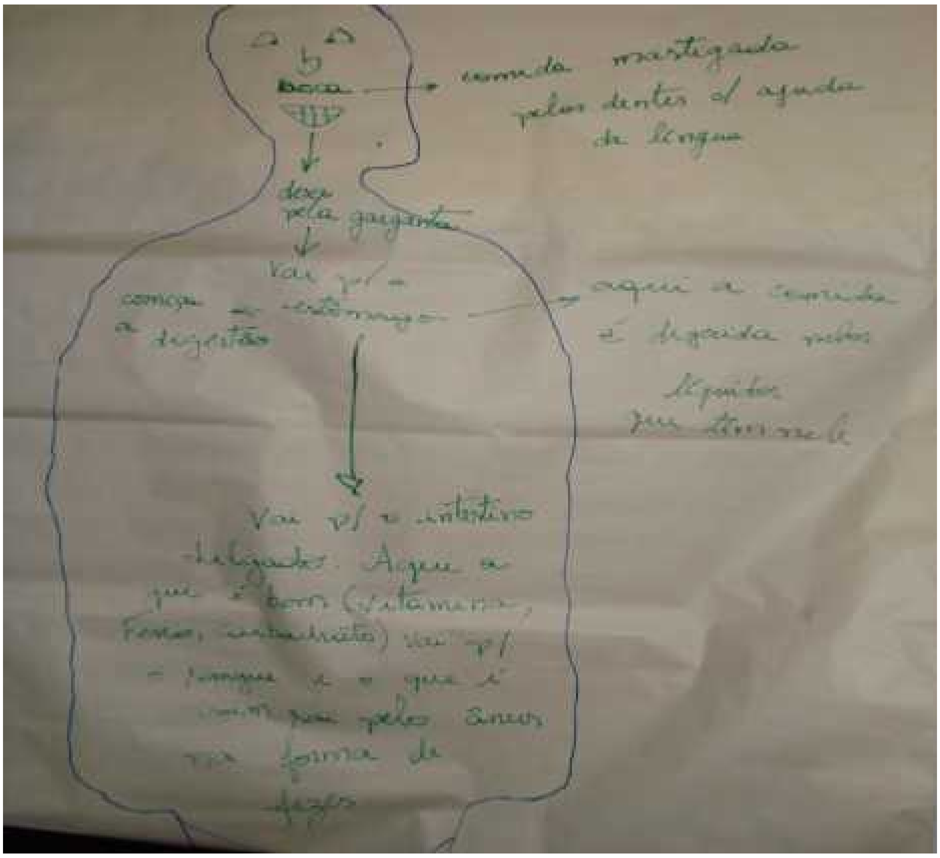

Fig. 2 – Students'_drawing about told the trajectory of the feeding.

But traces of authority approaches have been saw when the searcher putted only her point of view and only her voice was heard. In this episode a bigger interaction between searcher and students were done, with bigger relevancy to the student's initiative. However, the mainly objective of this study was the teacher's intentions. The problem was to engage students in the way intellectual and emotional to build meaning through the LO using.

However, the mainly objective of this study was the teacher's intentions. The problem was to engage students in the way intellectual and emotional to build meaning through the LO using. The students' visions about the digestive system of human being were explored by the oral and writing language, this last in the way of drawings. The LO introduced the scientific concepts. In this way, the technology was incorporated to the social plan of classroom. The simulations and interactive images from LO given support to the concepts' internalization and the building of students own meanings about the topics that were studied.

Beyond the dialogic/authority approaching, the simulations and interactive images' LO furnished metacognitive tools to aid in the building of meanings started the concepts exteriorization, as enunciated, and his posterior internalization. The internalized concepts could be watched when students named the organs of the digestive system in the final activity of the class.

During the searcher's intervention analyzed that to explore ideas about students' digestion watched that the signs that was presented by the students was only a reflex of theirs reality (BAKHTIN, 1986). In the intervention were explored students' ideas about theirs nourishment habits and about the act of to choke - a concept raised by the students. Starting this, the question selected about to choking trade the main expressed: the physician process of the closing of the glottis (Figure 3).

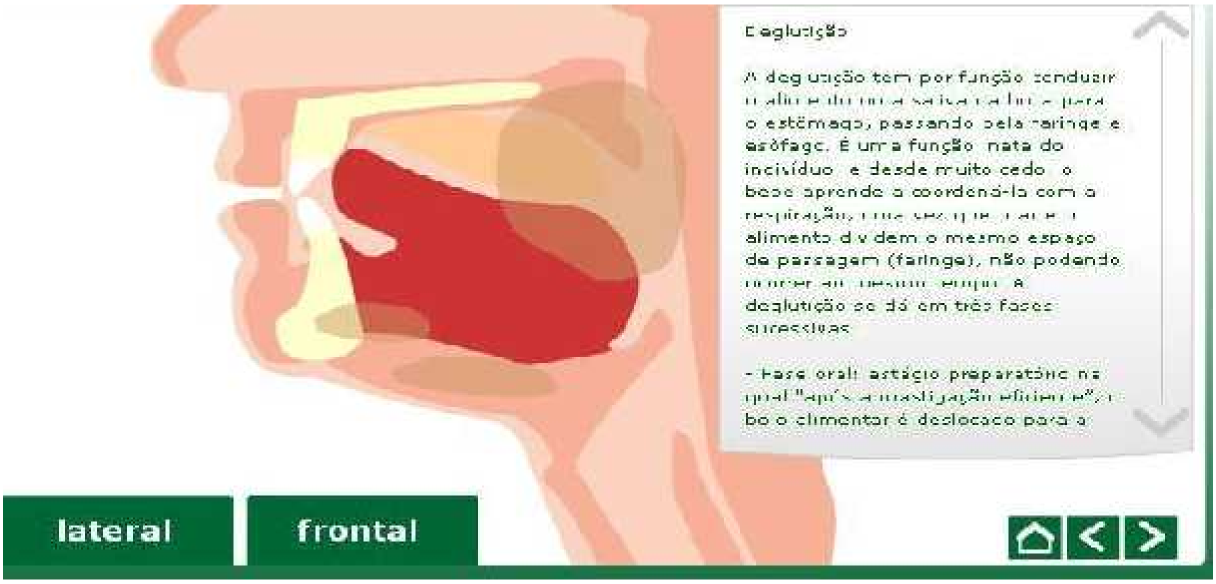

Fig. 3 – Physician process of the closing of the glottis screen visualization.

In this point was requested to the students that repeat the scientific concept. In this way, the internalizations' steps described by Vygotsky (2000) could be watched. To the repeating this concept the students start to re-organized the ideas of them. To Vygotsky (2000) an external activity is rebuilt and begins to happen internally. By the way students attributed the fact of feeling suffocated to the coming of nourishments through trachea with the sentence:

Student: *the nourishment comes through the wrong hole!*

Being follow by the exclamation:

Student: *Blame this we choke!* That means to them don't close the glottis.

CONCLUSIONS AND IMPLICATIONS

Ending, signs can be realized as internalizated since that all the sign is part of the reality that enunciated it, to Bakhtin (1986). This work was influenced by researchers that have studied the interactions in the sciences class and in the way as new meanings are developed through of ways of verbal and no-verbal expressions. Patterns of discuss that take advantage of others in the sciences classrooms are so several and likewise they consist in a genre of steady discuss that will be the focus of analyses of ours (MORTIMER and SCOTT, 2002). To sum up the results through done activities was possible to watch Bakhtin premise (1981) where the *sign opposite itself to another sign the conscience herself only can rise and assure itself like reality through material incarnation of signs*, however, students took conscience about concepts over bodies organs of digestive system when they named them in a draw in this way. students. Ending, it understood that the interactions that happen were so primary genre (students' speeches, prejudicing about scientifics concepts) and secondary genre. The discursive genre was presented in the whole LO was the secondary (ideological) genre. And so, the teacher intent to teach the content was concluded and a scientific discuss was done.

TWO GRAPHS DON'T MAKE A WHOLE: THE SYNTHESIS OF DISPARATE GRAPHS IN INQUIRY-BASED SCIENCE LEARNING

[3] Al-Qasemi High school, Israel

Abstract: A comparative synthesis of multiple graphs is a common practice in scientists' work as well as in everyday contexts. This process involves elements of a meta-analytic approach, such as computation of effect size measures. We present findings from classroom enactments in Israeli and Cypriot high schools, in which cultivating students' graph meta-analysis skills was one aspect of fostering scientific literacy through an inquiry-based learning environment on socio-scientific dilemmas. The topic of the environment was "How can we choose the best smoking cessation aid?" and it required students to compare four smoking cessation treatments using graphs modified from recently published scientific articles. The specific task which is the focus of this paper required students to merge data from two line graphs, in order to rank the treatments by their efficiency, defined as abstinence from smoking. In contrast with a previous pilot study, most of the students ranked the treatments correctly, and an examination of students' justification for their rankings indicated a significant improvement in the quality of arguments. A comparison of pre- and post-enactment responses to graph synthesis tasks showed a significant improvement but on the other hand indicated that graph synthesis is a demanding task for most of the students, even following a focused intervention. Our findings highlight the challenges that learners and teachers encountered and their implications for future instruction and design.

Keywords: inquiry-based learning, socio-scientific issues, graph-reading skills, graph synthesis, adapted primary literature

INTRODUCTION

Scientists conducting a literature review or lay-people searching the web often encounter the same conundrum: making sense of an abundance of data sources that provide partial answers to their question. This creates a need to compare and synthesize the different pieces of information into a coherent whole. For example, different scientific articles that deal with similar research questions may test different variables, or operationalize the same variables in different ways. In such cases, a simple aggregation of the information can yield erroneous conclusions. Instead, meta-analytic steps, such as using effect size to normalize findings to a common scale, need to be taken to juxtapose and synthesize the information.

Synthetic skills may be considered a subset of procedural scientific literacy skills (Bybee, 1997), because they involve credibility judgments and allocation of different weights to multiple data pieces. Despite the fact that the use of meta-analytic methods and effect size measures has become quite common in current scientific work, these issues are not typically addressed by high school curricula. In line with current definitions of scientific literacy (e.g., OECD/PISA, 2003) we believe that it is important to expose students to synthetic aspects of the scientific process, in addition to the more prevalent analytical aspects. However, by this we do not mean that students should be taught explicitly how to conduct a meta-analysis or how to compute effect sizes (i.e., how to "do science", Millar & Osborne; 1998), since this procedural knowledge is only relevant for a small minority of the students who will become scientists in the future. Instead, our objective was to confront students with situations which require data synthesis, and lead them to articulate a solution, using an inquiry-based approach. Specifically, we chose to focus on synthesis in the context of graph comprehension (Bertin, 1983) in a process we refer to as *graph meta-analysis*.

Graphs are central communication devices in most empirical reports, especially in science but in other contexts as well. Non-scientists encounter graphs on a daily basis at work, in the popular media and the internet, even in advertisements. We use the data represented by these graphs in order to draw conclusions and make decisions. We may use a graph to choose which cereal brand to buy, and we may use another graph to decide whether or not to spill sewage into the river. Not surprisingly, graph interpretation and production skills are emphasized in national science standards (NRC, 1996). However, several studies have shown, several studies have shown that full competence in reading and producing graphs is not achieved even by college and university graduates (Bowen, Roth, & McGinn, 1999; Leinhardt, Zaslavsky, & Stein, 1990). Bowen and Roth (2005) found that pre-service teachers, most of whom had a BSc degree, lacked basic skills in graph interpretation, and reached the sad conclusion that "preservice teachers do not seem to be ready to teach data collection and analysis in the way suggested by reform documents." These findings highlighted the need for concerted instructional attention on graphic literacy skills (di Sessa et al., 1991; Shah & Hoeffner, 2002). If making sense of a single graph is a difficult task, then having to glean information from a comparative synthesis of multiple graphs is even more challenging. This activity, which we refer to as *graph meta-analysis*, is a common feature in the work of scientists (and other professionals) when they analyze their own data or when they review data presented by others. A similar challenge is faced by citizens who encounter graphs when they make decisions about science-related issues based on information that they garner from news reports, web searches or other similar sources.

In order to present several graph comprehension tasks within a realistic scenario, we designed a web-based learning environment (LE) using the STOCHASMOS (Kyza & Constantinou, 2007) platform. The topic of the environment was "*How can we choose the best smoking cessation aid?*" This environment required students to compare four pharmacological smoking cessation treatments using data (graphs) modified from recently published scientific journal articles. This report focuses on a specific task that required students to synthesize data from two line graphs, in order to rank the treatments by their efficiency, measured as abstinence from smoking. Each graph contained data from a different clinical study, in which *only 2 or 3* treatments were compared, in addition to a placebo control group. Thus, the overall ranking of *four* available treatments required a process of meta-analysis, involving measures of effect size.

Our research questions were: (1) Will high-school students be able to solve graph synthesis tasks correctly, and if not, what will be their difficulties? (2) Can an inquiry activity serve as an effective tool for teaching students to handle such tasks? (3) Can elements in the design of the inquiry environment effectively fill in the role of the teacher and serve as learning scaffolds? (4) Is there a critical role for the teacher in such learning activities?

METHODS

A first version of the Nicotine Addiction LE was tested in a pilot study in one 10th grade class from a private school in a lower-middle SES Arab town (N=35). The revised version was tested the in two Israeli 10th grade classes and one Cypriot 11th grade class. One Israeli class was from the same Arabic-speaking school (class Q, N=22) and the other from a public school in a high SES Jewish suburb in central Israel (class R, N=16). The Cypriot class was from a high SES Greek-speaking school (class C, N=19). Students worked individually (class Q) or in groups of 2-3 students each. Only 49 students completed pre- and post-enactment individual assessment questionnaires. Two out of the three teacher participants (teachers of classes Q & C) were members of the Israeli and Cypriot development teams. We collected a variety of both process and pre/post data. Pertinent to the present report were the written responses to the "templates" (worksheets) in the computerized workspace, and responses on pre/postests. The pre/post-tests (two counterbalanced versions) included items on graph reading skills (some from PISA), items on conceptual knowledge about nicotine addiction and the use of control groups in clinical experiments, as well as items focusing specifically on graph synthesis.

RESULTS

We initially addressed these questions through a pilot study that presented students with the synthesis task, but with minimal scaffolding. Not surprisingly, the participants of the pilot study found the overall investigation very challenging and frustrating. Out of the whole class, only 11 pairs completed the synthesis task. None of the pairs ranked the medications correctly.Some of the specific challenges faced by students included: (a) Focusing on specific features of data in the line graph, e.g., differences between short-range and long-range effects of each treatment (8 out of 11 pairs); (b) Understanding the implication of different operationalizations for the same variable (all 11 pairs); and (c) Understanding the need to consider effect size (all 11 pairs). The teacher tried to provide scaffolding (Tabak, 2004) that was not provided by the computerized environment, through discussions with individual groups while they were working on their investigation, and through the asynchronous feedback notes that attach to the students' workspace. These mediations were not enough, so the teacher also held an impromptu whole class discussion that delved deeper into these issues. Obviously, the challenge for students became a challenge for the teacher. This challenge is amplified in settings where students work in small groups, each of which faces different obstacles in different time points, a situation that required the teacher to jump from one group to the other while other groups waited for their turn and sometimes lost their focus on the task and used the access to the internet for off-task activity. It is not surprising therefore that the teacher of the pilot class was exhausted at the end of each class, and this also affected her motivation to provide asynchronous feedback.

Following the results of the pilot study, we modified the contents of the LE. We added an introductory unit on placebo effects and control groups in clinical trials using a whole class discussion of case examples, and added prompting questions and hints in the text that accompanies the graphs in the LE. We made the graph representations easier to compare. Finally, we added special “synthesis templates” in the students’ computerized workspace that included questions designed to scaffold the analysis and synthesis of these graphs.

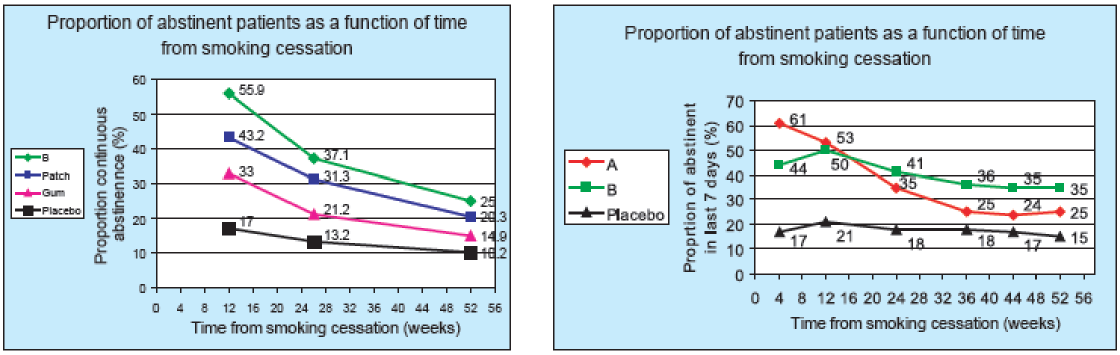

Figure 1: Graph synthesis task stimuli, following redesign

In contrast with the pilot study, most of the students ranked the medications correctly (58.3% compared to 0%). This difference was statistically significant (χ^2=10.69; p=0.001, Fisher's exact test). In class C, most of the teams did not complete the analysis of the smoking abstinence graphs due to time constraints, with the exception of two teams who proceeded ahead of their class but did not use the special the synthesis templates and, as expected, did not rank the treatments correctly. The highest frequency of correct ranking (85.7%) was observed in class Q, which was taught by the same teacher who taught the class of the pilot study. This teacher reported during the intervention that class Q was weaker than the pilot class, and its average grades in biology were significantly lower. Therefore it seems that differences in students' aptitude could not explain the differences between the pilot's results and those of the revised environment.

We also examined the arguments given by students to support their ranking. Even following the redesign of the environment, some students relied on the raw abstinence rates, and were unaware of the need to compute effect sizes, as can be seen in the following justification:

> "As we can see in the two graphs, the most efficient medication is B, because its results are the best, and the placebos in both graphs have the lowest results. We could compare them and therefore we merged the results. Medication A is ranked 2nd because in the other graph it is better".

Other students correctly justified their ranking by explaining how they computed the effect size:

> "I computed for each medication separately, according to the ratio between it and the placebo. I combined the results of the 1st and 2nd graphs, and the [medication] which got the highest ratio got the highest rank".

This justification was sometimes phrased with elaborate reference to the computation of ratios:

> "The computation principle: for every medication in the first part [=graph],divide the result at the end [=52 weeks] and divide it by the placebo. For example, medication B: 25/10=2.5. In the second part, divide by 15 instead of 10".

Some students understood that they had to compute a treatment to placebo ratio but apparently did not fully understand the meaning and utility of the result. For example, 4 students out of 14 from class Q computed the risk ratios of treatment B for the two studies, and then summed the result:

> "[For medication B] in the 1st table the ratio is 2.5 and in the 2nd table the ratio is 2.3, so the result is 4.8. The other ratios are computed as done for

> treatment B. At the end it is clear that treatment B is the best, with a ratio of 4.8 and the gum is the worst ratio – 1.5".

In order to quantify the quality of the justifications and compare between students' responses for the pilot stimuli and revised stimuli, we defined a scoring scheme and used it to score the justifications on a scale ranging from 0 to 10 (inter-rater reliability: 0.86 for pilot data, >0.9 for data following redesign). These scores indicated an improvement in the quality of arguments from an average of 1.45 (SD=0.80) to 3.79 (2.39). This difference was statistically significant (t-test, t=4.287, p<0.001).

There was more than a two-fold post- to pre-test increase in students' response to the graph synthesis question. But, these results still indicate that graph synthesis is a very challenging task, because even after the addition of specific instructional scaffolds only 36.7% of the students answered the posttest graph synthesis question correctly (compared to 16.3%). Similarly, we see advances, but not broad changes, in students' understanding of the synthesis process through their free-form responses explaining their solutions. We quantified the quality of students' justifications, and used a mixed design repeated measures ANOVA to test changes in justification quality. The main effect of time (pre/post intervention) was statistically significant ($F_{(1)}$=27.2, p<0.001). However, there was also a significant main effect of version order ($F_{(1)}$=8.29 , p<0.01) and a significant interaction between time and version order ($F_{(1)}$=15.02 , p<0.01). These effects are related to the fact that one version of the synthesis questions included an additional challenge for students, since it referred to an adverse (negative) effect of two medical treatments compared to placebo control. In such cases, the treatment with the larger effect size (i.e., treatment effect divided by control effect) should be considered worse than the treatment with the smaller effect size.

In order to assess whether the intervention improved students' conceptual knowledge about control groups in medical research, we used three multiple choice items in each version of the pre/post assessment battery, for two of which students were also required to justify their choice. Students showed an improvement from pre-intervention to post-intervention, from 37.4 (SD=20.3) to 48.2 (28.1) on a scale from 0 to 100 (t=2.51, 48 dof, p<0.05), but still did not internalize some of the central messages of the unit on control groups and placebo effects. For example, when asked about a case in which a treatment group was tested against a no-treatment control group, none of the students claimed that the observed effect may be solely due to a placebo effect. A repeated-measures ANOVA did not reveal any significant main effects of class and version order, or any significant interactions.

In order to assess whether the LE improves graph reading skills, we used two PISA tasks that involved graph reading but were not related in content to our LE (Greenhouse effect, task S114 and stickleback behavior, task S433). These tasks were included in the pre/post assessments of classes Q & R. Half of the students received the Greenhouse task prior to the enactment and the stickleback behavior task following the enactment, and the other half received the stimuli in reversed order. The answers were scored according to "Take the Test: Sample questions from OECD's PISA assessments" (OECD, 2009). Out of a possible score of 100 points, students improved from 41.96 (SD=30.47) to 58.93 (24.73). A paired t-test showed a significant difference between pre- and post-test (t=2.37, p<0.05). A repeated measures analysis also revealed a significant interaction with version order, indicating that the Stickleback assignment was more challenging than the Greenhouse.

CONCLUSIONS AND IMPLICATIONS

In conclusion, we are encouraged by our initial results that show that we have problematized the issue of graph synthesis for students. They recognize that one cannot simply aggregate disparate graphs without some form of adjustment. However, there is still much room for increasing students' understanding of the problems associated with simple aggregation, and with the specific procedures required for synthesizing graphs. The curricular and computer-based scaffolds we provided improved student learning, but these do not seem to be sufficient for broader and deeper learning gains. We hope that as a first step, our work will serve to include graph synthesis as an important part of the agenda for cultivating scientific literacy. In addition, we continue to explore how to scaffold and foster these skills, and how to integrate computer-based and teacher-provided scaffolds (Tabak, 2004).

ANALYSIS OF ELECTROCHEMICAL CELLS PROCESSES SIMULATIONS. STUDENTS' POINTS OF VIEW.

Jean Paul Ayina Bouni1, Suzane El Hage2, Soudani Olfa3, Soudani Mohamed4

[1234] S2HEP, EA 4148, Université de Lyon, Lyon F-69000, Université Lyon 1, Villeurbanne, F-69622, France

Abstract: We present a didactic and epistemological survey on the role and the relevance of the simulation in the understanding-modeling by the students of the working of the electro-chemical cells in closed circuit. Our step associates two approaches:

- on the one hand, an analysis of didactic and epistemological point of view of two applets of simulation of the electric conduction in an electro-chemical cell in closed circuit. One applet is conceived for teaching in Secondary school, the other for the university one.
- on the other hand, a semi-directive interview with students in the Upper Grade of Scientific Secondary School (France, 17-18 years old) explores both the observation of these applets, and the circulation of the carriers of loads and the selective drivers during the functioning of the cell.

We will debate about the didactic and epistemological relevance of the analyzed simulations that somehow seem to exceed the concrete experience, and to make the mechanisms of electro-chemical conductions "visible"/obvious to students.

Keywords: Electrochemical cell, electrical conduction, modeling, simulation.

BACKGROUND, FRAMEWORK, AND PURPOSE

Institutional context and theoretical frame

In the general education of physical sciences, it is usual to make reference to objects of the students' environment such as the electrochemical cells. Then electrochemical cell and their modeling are part of the 2002 French Chemical curriculum of Scientific Secondary School Upper Grade students (17-18 years old). The official instructions (BO) emphasize how to design effective model-based learning environments that actively involve students in their learning process. They recommend "*to simulate* [Computer simulation] *the evolution of the electrical behavior of a cell towards its balance state (discharge) by realizing many progress states of the system evolution corresponding to increasing values of the progress of reaction"*. It is in this institutional framework that the present study is registered.

Besides, the choice to use computer animation justifies itself in theory as follows: the approach of real life situations, in this case electrochemical cells, to enable students understand better, rests on the following principles: understand the functioning of a given phenomenological situation, is to represent it by a model (Halbwachs, on 1974). Modeling is the construction of a system of signs which substitutes itself to the physical situation in question and allows making operations of interpretation and forecasting (ibid). Besides, Peirce (1978), in its triadique conception of the sign, puts the iconic sign in the heart of the scientific work of conceptualisation and modeling. The physical situation in electrochemistry involves two interdependent dynamic phenomena (ohmic conduction and electrolytic conduction) and not only static structural aspects. So, the simulation of the phenomenon seems the most appropriate way of "materializing" numerically the system of signs (the model) as mobile iconic signs. It therefore ensures a function of semiotic imitation (Schaeffer, on 1999) of the imagined functioning of the electrochemical cells.

By gross simplification, we can say that simulation (computer animation) is a scrolling through the help of a computer of several images different from the plan (system of signs) of the electrochemical cells presented one after the other at different but very close instances like a cartoon. It gives the impression of a continuous progress in time of the functioning of the cell. This representational function also ensures (at least during the first steps of the approach of the phenomenon), a flashback towards its origin (the cell, the original, the imitated) (ibid). The question of the mastery of the parameters of simulation does not arise here: the students do not have the possibility to vary neither concentration, nor speed of the charge carriers, nor resistance in the circuit…). The simulation thus enables to see an invisible phenomenon with the naked eye and contributes, therefore, in its modeling. This capacity to be able to produce something to see rests in the fact that it operates a semiotic substitution of a system of signs (grade-related and symbolic) (Peirce, on 1978; Halbwachs (1974)) in the experimental, empirical device.

We suggest analyzing in what, and in which measure, the use of computer animation of an electrochemical cells can facilitate students in developing deep understanding of electrochemical concepts, and the modeling process itself in order to motivate them to learn more about chemistry.

Everyday cell versus the didactic cell

In the case of electrochemistry, where the object of study is mainly electrochemical cells, the student is found in front of a "didactic" object (fig.2a, fig.2b) different in all aspects from the view of the "everyday" object (fig.1). So, for the student, the link between both objects (didactic and everyday) is not immediate.

Indeed, for a student situated spontaneously (and often) at the empirical world (immediate perception), there is not common point between these two objects:

- The one of everyday use, is compact, in a single block (very fortunately for the convenience of its use in the everyday life), which the student ignores not only the constitution, before any lessons, but also and especially the functioning principle. This object, very practical, remains thus a real "black box", somewhere mysterious. Furthermore, it can appear under different geometrical forms, sizes and capacities, without necessarily having a proportional relationship between these three characteristics (fig.1).

Fig 1. picture of every day cell

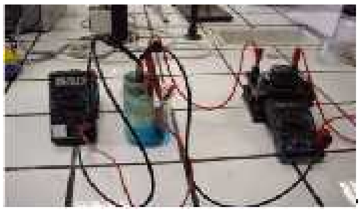

Fig 2a. Picture of didactic cell with porous wall.

Fig 2b. Picture of didactic cell with salt bridge jonction.

The other object called didactic, appears under two different forms: one constitutes of two separate vases either by the porosity of one of the vases which would then be placed in the other one, or by a porous wall, common to both vases (fig.2a). The other one constitutes of two separated beakers, a beaker containing a solution (generally solution of metallic ions (Mn^+) into which a metallic blade is inserted (the metal M), the other beaker similar to the first one, but with a different metal. For the student eyes, both beakers are interconnected by a kind of U "tube", installed upside down (!) in which there is a third solution again different from the two others (and which surprisingly could remain inside by its own without flowing in the beakers)

Each one of these didactic cells (figure 2a, 2b) is a type of macroscopic analogous model of everyday cells (figure 1); these imitations which permit to explicit its constitution and to ease understanding. In this way, the cell of fig.2b performs the same function as the cell of fig.2a, especially concerning electroneutrality. Unfortunately, they are not always presented as such. As we are going to explicit below, several researches have documented student's misconceptions concerning electrochemistry even after having received lessons (See bibliography). Most of them promote the use of simulation to build a model of the electrochemical cells. However, they have not implemented them in the same manner. There is therefore a scope to push the modeling process to a microscopic level to understand the functioning of a cell.

Difficulties in electrochemistry, and search of a remedy

The difficulties of students to understand electrochemical phenomena generally and the conduction of electric current in electrochemical cells in particular were the object of numerous research works all around the world. Several types of approaches were designed to try to understand the origins of these difficulties and to resolve them:

Garnett and Treagust (1992a, 1992b) identified indicators on the "reasoning" of students in electrochemistry by interviewing 32 students at the end of the high school cycle sector, after being taught electrochemistry. They think that "*in a solution, the electric current is due to a flow of electrons*", that "*electrons in solution are attracted by ions, and hence they move by passing from an ion to another*". Besides the problems which they have about the electric conduction, some students mistake electrodes, their polarity, as well as the name of the ions which are referred to them and the sign of the electric charge carried by them. These results were confirmed by Ogude and Bradley (on 1992, 1994) through a multiple choice question (MCQ) with 6900 students. These researches did not propose alternative didactic situations enabling to improve these conceptions and to develop them towards a satisfactory state of knowledge of the functioning of the electrochemical cell.

Based on the conceptions elaborated through previous works, Bouraoui and Chastrette (1999) led a study whose objective was to propose a remedy. For that purpose, they conducted a comparative study in Tunisia and in France on 83 high school students (16-18 years) and university students (in their second academic year in sciences) on these same phenomena. They displayed in front of the students the experimental assembly of an electrochemical cell during its functioning state, accompanied with its conventional diagram, making the link between both (a fast display of the model and the modeled object). The result of the questionnaire administered after the experiment is not convincing, and does not present a considerable evolution of the conceptions of the students to whom a misuse of the "electronic model" of conduction persists.

The limitation of the effect of this approach on the conceptions of students can be predictable. Indeed, on one hand, the diagram is already a part of the model (an iconic sign of the model), whilst its building rests with the student. Presenting students a complete diagram, is to postulate them the model and to invite them to make "the big step", difficult to realize for a learner suffering "handicaps" identified in the aforesaid researches. On the other hand, the diagram is congealed by nature; its construction does not always render "visible" a dynamic phenomenon, such as the movement of electrons and ions in the cell. We think on the contrary that it would be more relevant to make the building of the functioning cell diagram on the basis of the realized experiments, otherwise the diagram and the experimental set up would remain two worlds apart, which do not communicate between them. The multiplicity, and multiplication, of registers constitute a fundamental didactic variable in the elaboration of the models, provided that the student is involved in their construction.

Sanger and Greenbowe (on 1997, 2000), in a remedial didactic approach, opted for a display of the motionless diagram on one hand, and a dynamic numerical representation which they called computer simulation on the other hand. This experiment was done in two steps: first a display of computer simulation on the flow of electrons in metals, and then the flow of ions in aqueous solutions and the salt bridge. By proceeding in this manner, they thought that this division in time would be effective by allowing the students to focus on a single type of electric conduction once at the time to understand it better. Indeed, the students seem to have better understood the phenomenon of conduction in every type of conductor. This encouraging result shows concretely that simulation helps in the modeling of phenomena governing the functioning of an electrochemical cell. However, from their confession, these authors were a little bit surprised by the high number of still indecisive students, who manifested difficulties in associating both parts in the same continuous circuit, and thinking that electrons can flow freely in solution. If they suspect the quality of the simulation, and the short period of its display in front of the students, they do not seem to question the sequential presentation of the simulation. However, it can be a very interesting track to explore.

Besides, the eventuality of an additional difficulty which would be due to the junction by salt bridge (fig.2b) does not seem to have been explored in these researches, that is, pondering was not done on the relevance of a "model" of a cell with salt bridge in relation to a model where the junction is made by a porous wall. It is another question than we suggest dealing with in this contribution.

Following the continuity of these researches, our approach emits two main hypotheses:

The first one concerns exactly the purpose of the integrated character of the simulation of the functioning of cells, by opposition to the separated approach used by Sanger and Greenbowe (on 1997, 2000). It would be advisable then to select the most appropriate simulation for that purpose.

- The second concerns the comparison of the didactic relevance compared between both types of Daniel cells: that with the porous wall junction and that with the salt bridge junction. The second can be shown as an analogical model showing more of the flow of the charge carriers in the salt bridge.

Equipments and methods

Our equipments are two computer simulations on the functioning of cells, on one hand, and a paper questionnaire and pencil on the other hand. We were able to find, on the internet, two simulations which filled both the following conditions: (1) one of them corresponds to the didactic cell fig.2a. It is a simulation proposed by a high school teacher named Bruno HAAS (that we have indicated by the code SBH), and (2) the other one corresponds to the didactic cell fig.2b. It is a simulation proposed by university lecturers on the website of the on-line university (code: SUL).

Besides the correspondence with both didactic cells, these simulations satisfy the conditions of acceptability and accessibility developed by Tribollet and Fatet (2003) about the analysis of the numeric resources (of popularization or didactics) available on the internet.

For the experimentation, 22 students in the final year of scientific high school (17-18 years, Fr), having already followed lessons on cells with regard to the official curriculum were chosen on a voluntary basis. They thus saw the device in Fig.2b at least once. We submitted them to a pre test questionnaire, before they began viewing the simulations. Then, they were invited to watch freely on computer the simulations in question. And finally, we submitted them to the same questionnaire as the pretest, followed by a semi-directive interview on the use (their preference, impressions) on both simulations. The questionnaire is a multiple choice questions (MCQ) type. We shall explain here only the results obtained according to the abstract criteria of order and modeling. Also, we shall see the way in which the simulations were perceived by the students, as well as the effects on their reasoning.

SOME RESULTS AND DISCUSSION

According to our corpus, our results are two kinds: an analysis of the simulations in question, on one hand, and an analysis of the students' answer on the other hand.

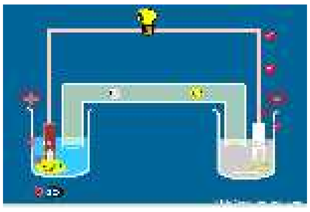
Analysis of the SBH and SUL simulations

If from the chemical point of view the electrochemical phenomenon remains the same in both types of cells (fig.2a, and fig.2b), the presence of the salt bridge seems better highlight the half-cells by separating them in space. This could, from this point of view, facilitate the understanding of the functioning of the cell.

Besides we compared the real functioning of these two cells, and verified that the presence of the salt bridge presents a major experimental inconvenience, namely the sharp increase of the internal resistance of the cell (300 times superior to that of the cell with junction by porous wall).

The SBH simulation

The SBH is elaborated in a single sequence of 36 seconds. It starts on an unanimated global plan and offers (to the chemist or the warned student) an overview of all the representative iconic signs of the functional structure of the cell (Fig.3). We also see that there is a single electron involved which flows outside the ohmic driver, parallel to it. It constitutes an abnormality in its imitative function of this conduction, not in what it badly sends backwards towards the imitated original, but in what it sends forward towards its effects (Schaeffer, on 1999) on the conceptualization of electroneutrality. Furthermore, this simulation is accompanied with no other semiotic register which could help the student to follow it without getting confused of the electric conduction.



T Fig 3 Picture of SBH computer simulation

Fig 4 Picture of SUL computer simulation

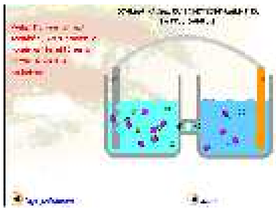


Fig 5 Picture of SUL computer simulation showing the flow of electric charges

This simulation (fig. 4 and 5) includes 55 sequences (among which 26 are animated), in 3 minutes and 23 seconds, associating observable macroscopic, such as the increase of the mass of the copper plate, the decrease of that of zinc, or still the color change of solutions, and the microscopic aspects (interpretations of the first ones) for which it is fundamentally intended.

We can blame this simulation for the absence of the interactive character of conceiving and building, which enables the student to practice and verify his own experiences.

Analysis of students' answers

The questionnaire used here is inspired by the questions formulated in the works previously quoted.

The pre-test gives, with some degree of accuracy, similar results to the researches of referenced works. For example, 40% of the students show difficulties to understand the flow of electrons and ions respectively in the ohmic conductors and the electrolytic conductors of the cell. Although the students already had a lesson on this part of their program, this results show the significance of the difficulties of students to identify the charge carriers and their respective flow sites when the cell debits. The teaching seems to have not targeted these difficulties to develop them.

It seems the free viewing of the simulation enabled to obtain a very encouraging result during post test (same questions with pre test). 80% of the students in TS (but not 100%) seem to have mastered the flow sites of the different charge carriers of electric current.

Questioned about the simulation which they prefer, the students choose without hesitation the SBH simulation. In the question "why do you choose the cell with salt bridge?" they argued that "it is clearer, we see better… the other one [that with the porous wall] is much too complicated. It takes a lot of time". Indeed, the SBH asks them for less concentration efforts because it lasts less than a minute, in a single sequence, especially since it seems to them that it presents exactly the same thing as the SUL, which is not the case. The students seem to disregard details which seem to them as secondary, such as the step of construction of the cell, and the progress of the underlying chemical reaction, in reference to the transformations of the material so simulated. Besides we could wonder if this preference is not influenced by the nature of the teaching they have already received on this subject, and where the cell with junction by salt bridge is the didactic example in the curriculum.

CONCLUSION

If the computer simulation plays an important role in the modeling of the physical situations, such as the functioning of the electrochemical cell, nevertheless its status at high school is one of a means which does not have to be confused with an objective (the modeling). The students do not participate in the construction of the simulation, which is an intellectual work of quite a different nature which could enable understand what distinguishes a model from reality of reference on one hand, and the simulation itself on the other hand.

The results of the post test are to be dealt with carefully, especially due to the pre test (which took place after the teaching of this theme) because the questionnaire was administered just after viewing the simulations. The students still thus had fresh memories filled with the images of the simulation.

But the purpose of the simulation and its effect on the development of students' conceptions remains undeniable. The students' preference of the SBH lets us think that they do not make reference only to the scientific knowledge to answer the questions. It also shows the importance of the ergonomic criteria, and other (time, the number of sequences, the neatness of the images, the size of the images, and the simplicity of the images) in the construction of a didactically effective and attractive simulation.

A RELATIONAL MODEL OF THE LEXICON TO DESCRIBE AND ANALYSE ECOLOGICAL CONTENTS IN PRIMARY SCHOOL TEXTBOOKS

Leonardo Beccarisi[1], Maria Cristina Tatano [1], Caterina Lorenzi[1]
[1] Department of Biology, University of Rome "Tor Vergata", ITALY

Abstract: The importance of ecological knowledge since childhood has been well stressed out in letterature concerning pro-environmental attitudes. Although some authors underline the key role of school textbooks in the process of scientific knowledge construction, the ecological contents in schools textbooks have been poorly studied. The aim of the present work is to project a computational procedure and to develop a model of primary school textbook lexicon to describe the structural organization of the document and to detect the weight of Ecology. The computational procedure has been projected to collect, to order to archive and lastly to process the data. To test the methodology, one of the most used italian textbooks series has been worked out. The model that has been obtained is a relational one. The relational models are, infact, flexible and interactive, and allow to explore the organization of the textbooks and to detect the weight of the contents. Indeed, the model provides a representation of the semantic structure of the document so that it can be aligned with other lexical resources and ecological domain ontologies.

Keywords: Computational lexicon, Ecology, Ontology, Primary School textbook, Relational model.

INTRODUCTION

It is important to encourage the study of Ecology in the early school years, because increasing environmental knowledge may result in more positive pro-environmental attitudes (Prokop & Tunnicliffe, 2008). Many Authors underline the importance of textbooks in science teaching in primary school (Chiappetta, Fillman & Sethna, 1991; Korfiatis, Stamou & Paraskevopoulos, 2004) for both teachers (Stern & Roseman, 2004) and students (Caravita, Margnelli, Valente & Luzi, 2007; Caravita et al., 2008). However, some Authors (Korfiatis et al., 2004; Caravita et al. 2007; Gambini, Pezzotti & Broglia, 2008) point out that Ecology is poorly represented in schools textbooks. During primary education, pupils are expected to develop increasingly more complex and systemic ideas about the living beings and their environment. Particularly, the italian curriculum for primary fifth grade includes aspects concerning biological systems and environmental systems such as ecosystems, their biotic and abiotic characteristics, the way human being can protect environment (Ministero della Pubblica Istruzione, 2007). It is than interesting to assess the real alignment of ecological contents of textbook and italian school curriculum.

The content analysis of textual documents require the use of methods to single out the useful features found in the text (Feldman & Sanger, 2007). Moreover, the development of a model is a necessary process when working in computer environment, since just a model enables to maintain the dynamism inherent in the linguistic-textual system of a document (Orlandi, 2010).

The relational approach tries to make explicit the structural organization of a document, which is implicit in models of other approaches, and describes how the terms extracted from texts are related to each other (Evens, 1988). Furthermore, as the conceptualization of basic ecological concepts and processes is an essential requirement in order to come to understand more complex ecological subjects of study, this approach allows to assess the exposure of children to ecological knowledge during the all five years of primary school. For this reason the content analysis of textual documents requires a flexible representation models for the assessment of contents of interest through the texts (Feldman & Sanger, 2007) as through the school time.

PURPOSE

The aim of the present work is to project a computational procedure and to develop a model of primary school textbook lexicon to describe the structural organization of the document and to detect the weight of Ecology.

MATERIAL AND METHOD

In order to assess the procedure, it has been processed one of the most used italian textbooks series, published by Giunti. Five books, one for each school grade have been analyzed, considering Geography, History and Science sections, for a total of 661 pages.
Each textbook is organized into well distinct and hierarchically nested structural parts (hereafter Visual Blocks or VBs). Main VBs are represented by thematic sections, each divided into chapters, and these subdivided into paragraphs that are associated with the paratext VBs, such as boxes, pictures and insets. The paratext is important from the standpoint of learning as they give the student the opportunity to study in-depth and to check understanding. Every VB is thematically homogeneous. It is also important to stress that the terms of subject content, considered important by the Author (hereafter Relevant Terms or RTs) are highlighted by special fonts in both text and schemes. Each textbooks series results from editorial decisions on the layout and organization of information. Despite this diversity, it is possible to trace the variety of VBs of the different textbooks series at a general VB types taxonomy. The detection of RTs is implemented in the model as the representation of the content of a textbook. The VB types taxonomy is intended to provide criteria for the classification of VBs. The lexical relations between the RTs contained in VBs are inferred based on the hierarchical relationships between VBs.

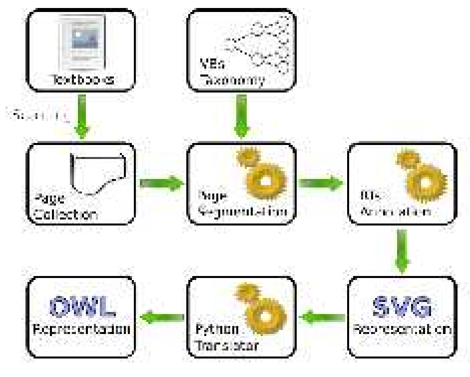

Figure 1. The computational process.

The Figure 1 illustrates a diagram representative of the computational procedure. The process is interactive and requires the intervention of a human agent. The book pages are scanned and raster images produced are collected in an archive. Each page is split up into constituent VBs

through visual segmentation. To this end, each VB is recognized by its distinctive characteristics and classified with reference to the VB types taxonomy. Every VB identified is annotated with the RTs that are contained in it.
Page segmentation and RTs annotation are performed with a vector graphics editor like Inkscape (http://inkscape.org), which is based on the W3C SVG, derived from the XML. A page raster image is imported into the software user interface, and every VB is bounded by a polygon that the software automatically translates into XML. Then, using the XML editor integrated in Inkscape, the VBs are annotated typing the respective RTs in. The lexical relation between the terms are defined with the RTs annotation. The RTs of a higher order VB subsume the RTs of the lower order VBs. This rule generates a tree structure of the RTs of the page. The annotated SVG file is then processed with an *ad hoc* Python (http://www.python.org) script, which implements an XML parser, which can combine RTs trees of different pages and can optionally translates outcomes in OWL format, a standard ontology modelling language of the World WideWeb Consortium (http://www.w3.org/).
The combination of different RTs trees is done through identification and connection of equal RTs. The result is a directed graph where each node is represented by a distinctive RT and edges depend on how the pages have been segmented. This structure is analyzed using measures rooted in graph theory (Bang-Jensen & Gutin, 2007). With these measures, the general organization of each graph and the topological properties of individual concepts are detected.

RESULTS

The graph obtained consists in 2009 nodes and 4816 edges and has a diameter of 8 connections.
Ecology, for example, explicitly appears only once and has a node degree of 1. Moreover, *Ecology* has an eccentricity of 7 and a diameter of 8.
Figure 2 shows a RTs tree resulting from segmentation process of a page in the Giunti Scuola textbooks series.

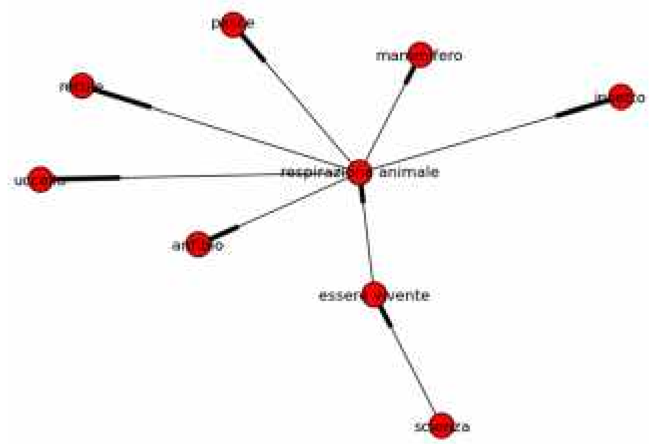

Figure 2. An RTs tree.

Figure 3 shows the graph obtained by the combination of the RTs tree of Figure 2 with the RTs tree of the following page. The two original trees have in common the RTs of the section title, “scienza” (*science*), the chapter title, “essere vivente” (*living being*), and a group of terms including “scheletro” (*skeleton*), “invertebrato” (*invertebrate*), etc.

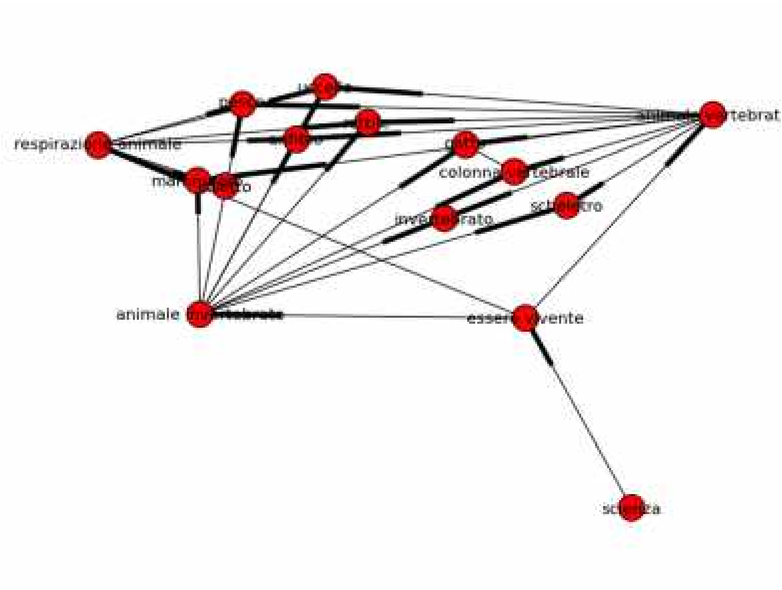

Figure 3. Graph resulting from the combination of two RTs tree .

Combining RTs trees sequentially and orderly, it is possible to analize the evolution of each graph measure with the flow of pages. For example, Figure 4 shows the evolution of graph diameter (by definition, the smallest of all shortest path lengths of the graph) resulting from the gradual combination of the pages, from the first page of first year textbook until the last page of the fifth year textbook. Similarly, Figure 5 illustrates the evolution of the eccentricity of the two terms “animale” (*animal*) and “pianta” (*plant*).

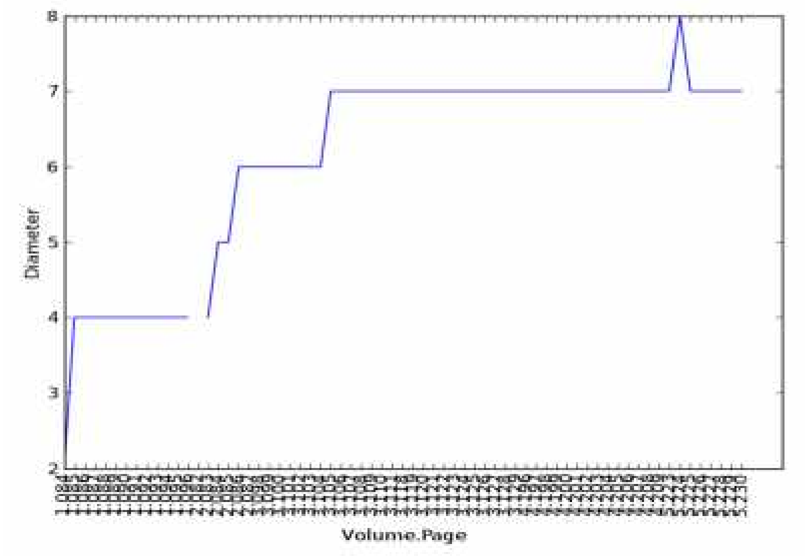

Figure 4. Graph diameter evolution.

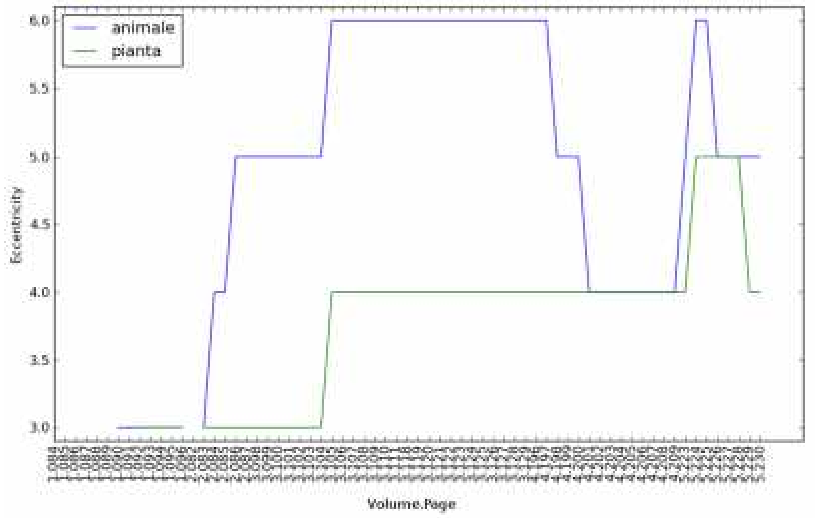

Figure 5. Evolution of eccentricities of the "animal" and "plant" nodes.

DISCUSSION AND CONCLUSION

The model seems to be suitable to describe the structural organization of the textbooks and to detect the weight of Ecology within them. Therefore, it allows to assess the children's exposure to ecological concepts during the five primary school years.

Furthermore, the analysis of the network at every stage of its evolution allows to evaluate when and how ecological concepts are introduced and their progressive differentiation. This offers interesting pedagogical interpretations analizing different disciplines presented into the same textbook and comparing different textbook series. The model is also flexible and can be aligned with ecological domain ontologies (Thiagarajan, Manjunath & Stomptner, 2008; Prèvot, Borgo & Oltramari, 2010) This will allow to measure the distances between the ecological contents detected and a more general ecological domain. Our current research is proceeding also forward the application of the relational model to obtain semantic relatedness measures that can be assessed in a pedagogical point of view.

Abstract: This research described the development of the Vegetation Interaction Game, a new digital game on the theme of vegetation succession. An evaluation experiment targeting elementary school students was conducted in order to verify the efficacy of this game as a learning-aid tool. The results of the knowledge and understanding test, a survey on the degree of immersion and a survey on the user-friendliness of the interface revealed that this game (1) supported children in their knowledge acquisition and understanding of vegetation succession, (2) helped children become immersed, and (3) provided children with a user interface that could be understood easily.

Keywords: Digital game, Vegetation succession, Role play, Elementary school, Environmental learning

BACKGROUND AND THEORETICAL FRAMEWORK

In science education, digital games have become one of the more effective learning tools. In such a learning environment, a learner can acquire scientific knowledge through the process of role-playing in the game. For example, simulation in a game can reveal the phenomena and processes of the microscopic motions of atoms and molecules, as well as macroscopic movements, and large temporal-scale phenomena.

Clark et al. (2009) reviewed preceding studies on digital learning-aid games in order to verify the efficacy of this game as a learning-aid tool. According to this review, major characteristics of such games included the players becoming immersed in the game by entering the character of the game, acquiring new knowledge as the game progresses, or applying the acquired knowledge as the game unfolds. Many digital games have been developed as learning aids in science education (for example, Barab & Dede, 2007; Collera, 2000; Dede, 2009). However, a game themed on vegetation succession in forests did not previously exist.

In this study, we developed a new digital game themed on vegetation succession. Vegetation succession is a phenomenon wherein the numbers and types of plants in a forest undergo transition during a certain time period. This phenomenon occurs largely due to substantial disturbances such as tree cutting or landslides, and interactions between certain types of plants in the forest. It takes many years to complete one succession. A digital game themed on vegetation succession appears to be very useful for students to understand such large temporal-scale phenomena.

PURPOSE OF THE STUDY

The aim of this research was to develop the Vegetation Interaction Game, a new game themed on vegetation succession, and to evaluate its efficacy. This game employs the role-playing board game format where each player is represented by a token and the game progresses by advancing these tokens along the squares on the board. The player that advances his/her token the most wins the game. An evaluation experiment targeting elementary school students was conducted in order to verify the efficacy of this game. The following three questions were posed in this research:

(1) Does the Vegetation Interaction Game support children in understanding vegetation succession?

(2) Is the Vegetation Interaction Game something children can become immersed?

(3) Is the interface of the Vegetation Interaction Game easy to understand for children?

DEVELOPMENT OF THE VEGETATION INTERACTION GAME

The Vegetation Interaction Game represents what a real vegetation succession looks like. A phytosociologist who is an expert on the Mt. Rokko area in the western Japan was the principal consultant of this game. Figure 1 shows the main window of the digital game. Six pieces represent six characteristic plants that grow in the Mt. Rokko region. The six plants include two early succession plants, Red small berry (*Rubus microphyllus* L. fil.) and Japanese Mallotus (*Mallotus japonicus* (Thunb. ex Murray) Mueller-Arg.); two middle succession plants, Red Pine (*Pinus densiflora* Sieb. et Zucc.) and Quercus oak (*Quercus serrata Thunb.* ex. Muuray); and two late succession plants, Longstalk holly (*Ilex pedunculosa* Miq.) and Castanopsis evergreen oak (*Castanopsis sieboldii* (Makino) Hatusima ex Yamazaki et Masiba). The central part of main window houses the following components of the game: a deck of event cards (Fig. 1-a) and a visualization screen to show vegetation succession according to the progress of the game (Fig. 1-b). Players can switch this vegetation succession visualization screen to show only one plant to focus on that plant.

If more than one piece takes the same position on the grid, the competitiveness for the light is either strong or poor between the plants; that is, the ‘interaction’ between the plants, as shown in Fig. 2. We set the event cards to correspond to types of disturbances that could possibly occur in the Mt. Rokko region. There are six such event cards: two large disturbances—tree cutting, landslide; two small disturbances—wild boar and pine longicorn-nematode disease; and no disturbances—fair weather and rain. These events influence vegetation succession.

Six players can participate in any one game. Each player handles one piece. Players draw event cards, one at a time, by clicking the event cards in turn. When a plant piece advances ahead on the board grids, it implies that the plant is dominant in that particular environment. Each piece moves according to the number of grids that the current event card indicates or if there is an interaction between the plants. The game finishes when all event cards are drawn.

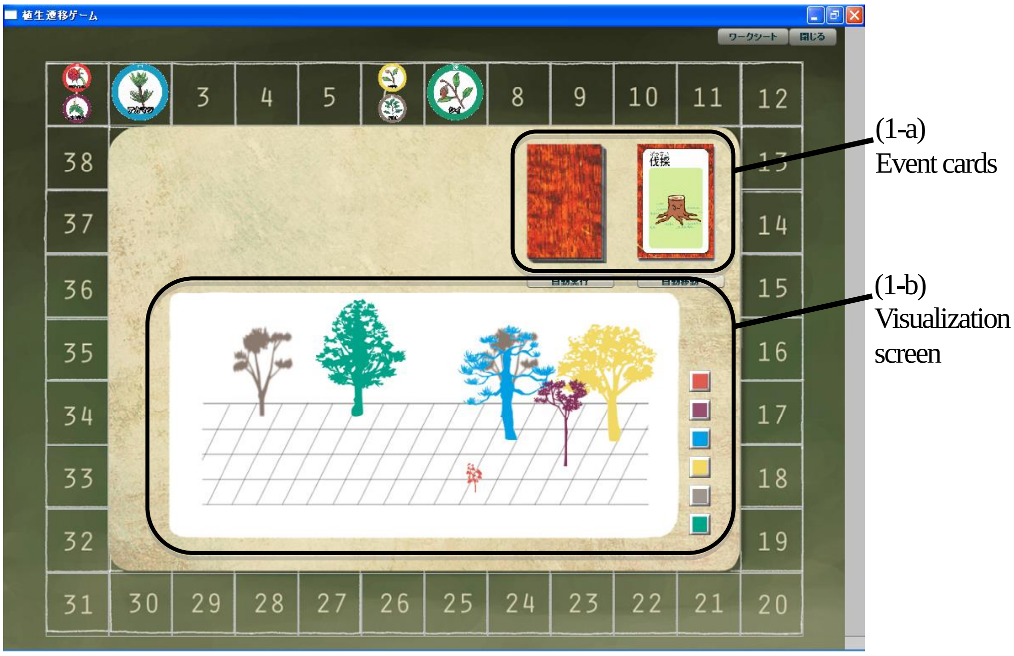

Fig 1. Main Window

Fig 2. Interaction between plants

EVALUATION OF THE GAME: RESEARCH DESIGN AND METHODOLOGY

Knowledge and understanding test

A knowledge and understanding test on the same topics was administered to 36 children before and after they played the game. The test consisted of a total of 18 questions on the understanding of 'influence of disturbances' and 'interaction among plants'; both the pre-test and the post-test were graded out of a maximum score of 18.

Survey on the degree of immersion

A survey on the degree of immersion was conducted using questionnaires targeting 36 children. There were a total of 16 questions and children were asked to choose one of four levels of responses for each question.

Survey on the degree of user-friendliness

A survey on the degree of user-friendliness targeted 17 randomly selected children. The two questions were 'was the visualization screen of the interface easy to understand?' and 'was the interaction among plants easy to understand?' Approximately 10 minutes were spent on each child. In the analysis, the numbers of 'children who gave only positive answers,' 'children who gave both positive and negative answers,' 'children who gave only negative answers,' and 'children who did not answer' were counted for each question.

DATA ANALYSIS AND RESEARCH FINDINGS

Knowledge and understanding test

The average scores were 5.00 (standard deviation 2.63) for the pre-test, and 11.47 (standard deviation 2.31) for the post-test. Using the Wilcoxon signed-rank test, it was revealed that the post-test yielded significantly higher scores (z=-5.14, p<.01).

Survey on the degree of immersion

Table 1 shows the result of the survey on the degree of immersion. 'Definitely' and 'I think so' were considered positive answers, and 'Not really' and 'Definitely not' were considered negative answers. Fisher's exact test (1 by 2) was conducted in order to examine the answer trends. The results revealed that the number of positive answers exceeded the number of negative answers in every question .

Game Interview

'Children who gave only positive answers' and other children were tallied and Fisher's exact test (1 by 2) was conducted in order to examine the answer trends of the children. The results revealed that the number of 'children who gave only positive answers' significantly exceeded the number of all other children.

CONCLUSIONS AND IMPLICATIONS

This research was used to develop the Vegetation Interaction Game using vegetation succession as the theme. Further, a demonstration experiment was conducted at an elementary school in order to verify the efficacy of the game. Three tests/surveys concluded that the Vegetation Interaction Game, as a learning-aid tool for science education, possesses the digital-game characteristic of immersing the players in the game while supporting their knowledge acquisition and understanding of the scientific phenomenon of vegetation succession. Clark et al. (2009) mentioned that the effectiveness of digital games in supporting children's learning is that games have rules and goals that encourage children's becoming immersed in the game and simulations that accelerate children to imagine macro/microscopic, or large temporal-scale scientific phenomena. It can be said that the Vegetation Interaction Game developed in this study is effective in supporting children's learning of role-playing and visualization screens.

This research succeeded in developing a new digital game that supports science education, themed on an unprecedented topic of the scientific phenomenon known as vegetation succession. Vegetation succession is a phenomenon where the species and number of dominating plants change within a certain forest environment. In this day and age, where harmonious coexistence of mankind and nature is a major goal, it is important to provide children the opportunity to understand and gain first-hand experience of the vegetation succession in forests through science education. The implication of this research is that digital games can be effective tools for supporting the learning of these types of phenomena.

NOTES

This research is funded by a Grant-in-Aid for Scientific Research (A) (No. 20240068) for Tomoyuki Nogami and Hayao Nakayama Foundation for Science & Technology and Culture for Akiko Deguchi.

Abstract: Molecular visualization (MV) software enable a user to view a molecular model via a computer. They are regularly used by researchers in biology in many ways and the willingness on the behalf of the institution was strong to very quickly integrate the MV software in biology education.
Our work here focuses on the transposition of a scientific tool, the MV software, in the educational world and specifically on their use with students. It is relevant to study their conception and use in the classroom because several studies have shown that they can improve the understanding of molecular concepts among learners.
In order to study this use, we employed three types of indirect approaches, analysis of the francophone web, analysis of textbooks from three editors since 1992 and analysis of interviews conducted with five French biology teachers who use MV software.
The results obtained by these three approaches converge and indicate that there has been the production of a scholar tool from a scientific tool. More specifically, we observe that almost only one software is used, some molecules related to this software and some activities designed using this software and these molecules. However these activities remain illustrative whereas one might have expected some of them to enhance an investigation posture. Furthermore, the origin and status of molecular models are not or very little explained. And this may lead the students to a misconception of the molecular models.

Keywords: Biology education, ICT, molecular model, use of molecular visualization software

BACKGROUND, FRAMEWORK, AND PURPOSE

In the teaching of biology, in the early 1990's, there was a willingness of the institution to be as close as possible to the scientific techniques developed in laboratories [Demounem 1992].

Our framework is based on the idea developed by Martinand (1989) that the academic discipline refers to social out of academic discipline defined as "social practical of references" and particularly scientific practice for science education. We are also study how the computerization of a discipline works, a field described by Linn in 2003.

Here we are going to investigate the result of the transposition of a scientific tool into the educational world. For that, we are going to focus on the case of molecular visualization (MV).

In the early 1950s, biologists realized the first models of biological macromolecules. Knowing the structure of these macromolecules represents a significant challenge given their small size, we understand it is necessary to use various experimental techniques (such as X-ray crystallography) to get information on the molecule and thus build up a model (see figure 1). The first models were visualized using large physical models (several meters). But it's in 1966 that Cyrus Levinthal and his team [Levinthal 66] realized the first MV through a computer. Subsequently, the software and computers have improved and, in 1993, *RasMol*, a MV software able to run on a personal computer, is put into the public domain which has brought this technology formerly restricted to a few research centers at the door (financially speaking) of all. For further details on the historic of MV, see Matz & Francoeur (2010).

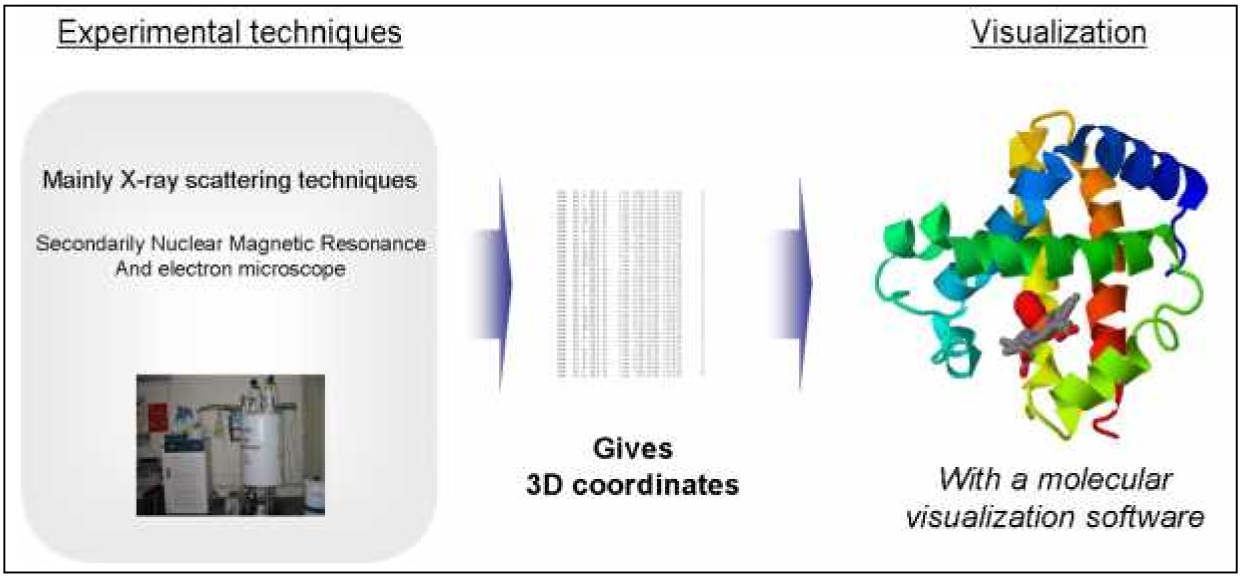

Figure 1: Way of obtaining a 3D model of a molecule.
And a representation that can be observed with a molecular visualization software.

Today, the MV represents a major challenge in biology given the importance of knowing the structure of molecules. Indeed, the structure of biological macromolecules dictates their functions, that's why the MV is used in many parts of biology as [Watson & al. 09] retail it. They are eg used by every researcher who wishes to produce an image of the molecule(s) he studies to illustrate his point in an article.

Martz, professor emeritus at the MIT, greatly encourages the use of MV software in education through his website [Matz, 10] that may be the biggest website for MV resources for teaching purpose. In France, analysis of the national curriculum of "sciences de la vie et de la terre" (SVT), the equivalent of biology and geology, indicates that MV is tucked into this curriculum with a recommended use of MV software for some practical work. In scientific 11th grade (16 years old), as early as the 1993-1994 school year, that is to say as soon as the MV software was available to the general public and, in scientific 12th grade (17 years old), from the year 2000 and, for 10th grade (15 years old), in 2010. Furthermore, these MV software figure in the test to graduate from high school through the evaluation of experimental capacity in SVT, being present in approximately 10 % of the subjects offered.

The work presented here is part of a PhD interested by the transposition of a scientific tool, the MV software, into the educational world.

RATIONALE

As Yarden and Yarden (2009) show it with the use of a PCR animation as a visualization tool, the animated tool provides “a significant advantage to the students who used it over those who used still images”. So animations can facilitate the comprehension of molecular processes.

Ferk, Vrtacnik, Blejec and Grill (2003) show on students from 13 to 25 that, on one hand, they have a better understanding of molecular models with representations on computer software with a MV software than with a 2D representation with a photograph or a schematic representation of molecular model. On the other hand, the correct perception of the 3D structure of the molecule is crucial for all subsequent mental operations related to molecular structures.

In the same vein, Berry and Baker (2010) show that “it is often extremely difficult to impart an understanding of complex three-dimensional relationships when using two-dimensional projection screens” and therefore molecular visualization software make “it possible to bring spatial relationships to life with three-dimensional images”.

These studies thus show that MV software can be beneficial to the teaching of molecular concepts; therefore it is relevant to observe how the software is used in high school during SVT courses.

METHODS

It is difficult to get information on the use of software in the educational system in France. Indeed, there are no organisms or reports that gather information on this topic. That’s why we had to use indirect approaches to get an idea of the result of the transposition of MV software in high schools in biology in France.

First we assumed that there would be some marks of this use on the French web. That’s why we investigated it to find some hints that would show the use that can be done with MV software. We started to analyze the websites that are supposed to help teachers. These websites are the 35 academic sites (an academy is an administrative district of the French minister of national education, each one has is its own website with several resources for the teachers) and the site of the “National Institute for Educational Research” (INRP) through the section managed by the team of “Continuous Updating of Knowledge of Science Teachers” (ACCES) [ACCES 10]. And after, we used the search engine *Google* to find other websites that could give us some more information.

Second we analyzed textbooks of five different publishers (Bordas, Hatier, Nathan, Magnard and Hachette) from 1992 to 2010. Indeed, textbooks are very often used by French teachers to give their lessons.

Finally, we conducted interviews with six French high school (grade 10, 11 and 12 – age 15 to 18) SVT teachers known to be expert in the use of MV software. The questions asked aimed at knowing which molecular visualization software they used and why. How they discovered the software. The activities they have done with the software. The problems they face when using the software. And the possible improvement they could feel when using the software.

RESULTS

Analysis of the francophone web

The analysis of the francophone web showed that beside the academic sites and the site of the “National Institute for Educational Research” (INRP), information about MV software for teaching is not or barely not on other French websites.

On academic sites, the most often emphasized MV software is *RasTop* that was created in 1996 from *RasMol* in order to be adapted to the educational world. It is possible to find, on some academic website, activities using MV software intended to be made during practical work to introduce molecular concepts (like the structure of DNA). But they almost all refer to the section ACCES of the website of the INRP.

On the ACCES section, there are many information about the *RasTop* software: a fairly complete description of the software, molecules to download and examples of possible activities with this software. It also contains information on *RasMol* but far less significant.

We can also notice “Library of Molecules” website [Librairie de Molécules 10], a cooperative site, in which 11 academies participate, which provides molecular models selected by teachers for a classroom use. Nevertheless, website activity so far remains low.

There is thus, on the French web, a key role played by the ACCES section. With a focus on one software, *RasTop*, a pool of molecules available which has slightly varied from the one proposed by ACCES in the early 2000s and a small number of activities that also have slightly varied from the early 2000s. There is only a few opening on the English websites like the site of the *Protein Data Bank* (PDB) website which is the single worldwide repository of information about the 3D structures of large biological molecules. These results were reinforced by an analysis of user queries on the *Google* search engine and user requests to access to the site of the INRP (Author and Blondel, 2011). Finally it is important to note that, nowhere on the French web, the origin of molecular models and how to obtain them is questioned.

Analysis of textbooks

The textbook analyses showed that the images of molecular models presented are not or barely not exploitable because of the lack of precise data (no caption, unspecified representation, no scale, etc.). Some textbooks also offer activities similar to those offered on the web francophone. Finally, in the same way as on the francophone web, neither the origin of molecular models nor its status is explained. So the textbooks are insufficient in themselves to address the MV.

There is also an evolution during time, in the latest textbooks there are a bit more topics related to molecular visualization software. And there is the emergence of technical sheets on *RasTop* in the most recent textbooks.

Analysis of the interviews with the teachers

The analysis of the interviews with the teachers showed that they use the *RasTop* software during practical work to realize activities such as those described on the francophone web. They say they spend little time on the explanation of molecular models. They indicate that these molecular models are not always very clear for the students who may sometimes feel like observing a molecule and not observing a model constructed by scientists.

Question: Do students clearly understand the conception of molecular model?

Teacher: I am not sure, I am not sure at all, for example sometimes they believe that they are watching a real molecule in real-time and not a model…

Teachers indicate they regret the lack of molecules and examples available to use MV software.

CONCLUSIONS AND IMPLICATIONS

All the results obtained with the different approaches converge to say that there has been fabrication of a scholar tool with a reduction phenomenon on one software (*RasTop*), mainly one website (the section ACCES of the website of the INRP), few molecules and some activities. In addition, these activities remain illustrative whereas one might have expected some of them to enhance an investigation posture. And it seems that since 2002, the school practices are stabilized and did not change a lot.

Furthermore, it is important to note that the origin and status of molecular models are not or very little explained. Perhaps this leads to a misconception from the students about the molecular models as indicated in the speech of teachers. As Linn (2003) suggests it, perhaps visualizations confuse rather than inform learners.

PERSPECTIVES

It could be possible to study the “social practical of references” to propose some new activity that could renew the use of these software in classes. And thus design new activities with the collaboration of teachers.

We might also consider studying how molecular visualization is used in education in other countries, for example in the US.

COHERENCE OF AN ICT-USING TEACHING SEQUENCE: A CASE STUDY IN OPTICS AT LOWER SECONDARY SCHOOL

EL HAGE Suzane[1], *BUTY Christian*[2]
[1]UMR ICAR (Université Lyon 2, CNRS, ENS de Lyon)
[2]EA ECP (Université Lyon 2, ENS de Lyon, Université de Saint-Etienne)

Abstract: This communication reports a case study based on a discourse analysis in an ordinary classroom, at grade 8 in a lower-secondary school in France, during a teaching sequence in elementary Optics. It particularly focuses on a part of the last session, where the eye is presented as an optical system using a lens, the focal length of which is variable. For this part, the teacher is using a computer-based simulation. The teacher's discourse is analysed from a threefold point of view: the modelling processes; the conversions between several semiotic registers; the coherence between this session and previous activities in the teaching sequence. From all these points of views, the use of an ICT tool offers new learning opportunities to students, or strengthens learning opportunities already offered.

Keywords: ICT, Coherence, semiotic representations, modelling processes, affordance.

1. INTRODUCTION

ICT-based tools have reached a high level of use in science teaching in developed countries; they have multiple uses (among different typologies, see for example Pinto and col., 2010). This use can be seen and studied more specifically, for instance when an ICT-based device is chosen by the teacher to fulfil a specified task, at a given moment of a teaching sequence. As far as students' learning is taken into consideration, the long-scale effects that is, the coherence of the ICT use regarding the other parts of the teaching sequence, must be analysed as well: what is the role of an ICT device in a teaching sequence? Is it used to introduce new notions or to reinforce concepts that have already been studied?

The theoretical tools that we shall use in this case study take into account the multimodal dimension in science teaching and divide among three elements: the modelling processes, the semiotic registers and the affordances or learning opportunities.

2. THEORETICAL FRAMEWORK

2.1. Modelling processes

Models and modelling are an essential dimension in science teaching. Tiberghien (1994) distinguishes between two worlds in teaching/learning physics. She defines:
- the world of objects / events as knowledge elements that refer to the observable and material world,
- the world of models or theories, as qualitative or quantitative notions and procedures that correspond to the generalizable aspects of the studied situation.

From this epistemological point of view, physics teaching can be considered fundamentally as a matter of modelling processes, of establishing meaningful links between “the world of objects and events” and “the world of theories and models”.
Very often, ICT-based tools represent models of empirical realities, and one of the tasks of the teacher is to make this status clear for the students. For instance, in our case, the software used in physics (Cabri-Géomètre[1]) obeys the rules of physics and its representations belong to the world of theories / models.

2.2. Semiotic registers (semiotic representations)

Science classroom discourse is a particular one. It is multimodal in principle (Lemke, 1998) and uses several semiotic registers. Duval (1995) defines the semiotic registers in the following way: "they are the productions made by the use of signs (utterances in natural language, algebraic formulas, graphs, geometrical figures…)".

When using ICT in science classroom, many modes of representation, many “semiotic register” are used in the classroom discourse; the dynamic graphical representations, which are the core of most ICT-based tools, must be articulated with natural language (words and gestures as well), or static graphical representations (drawings or schemas on the blackboard, for example), or mathematical symbolism.

Duval defines some semiotics registers in mathematics education. We take in the following semiotic registers very often used in teaching physics:

- The register of natural language: it is the primary tool used before and / or during the acquisition of scientific vocabulary. This register is flexible that is, used in the world of objects / events, the world of theories / models and to make a link between the two worlds.

- The register that contains drawings, diagrams, and graphs:

a- a drawing is an "exact representation of the shape of an object" (Davy & Doulin, 1991);

b- a schema is a representation of a referent. It can be non-figurative and figurative. A figurative schema refers to something sensible, visual and perceived while a non-figurative schema designates a mental referent. (Estivales, 2003, page 56).

2.3. Affordance versus Learning opportunity

The psychologist James Gibson proposed the term “affordance”, in his ecological theory of perception (Gibson, 1979). He noted that the affordance depends on interactions between the animal and its environment: “*affordances as what the environment offers the organism”*.

In the field of ICT-based science education, Webb (2005) expresses a definition for the notion of affordance inherited from Gibson: “*In an ICT-supported learning environment affordances are provided by interactions between the hardware, software, other resources, teachers and other students*” (Webb 2005, p.707).

We consider as meaningful to introduce a distinction between two phases of teacher’s activity when implementing an ICT-based activity in the class, regarding the coherence of the teaching sequence and the effects on learning. This distinction is a consequence of our socio-cultural point of view on science learning, which gives a key role to social interactions in the construction of knowledge.

---

[1] www.cabri.com

When a teacher plans to use an ICT-based tool in a teaching session, he or she first chooses the software (or special functionalities of the software), depending on the school equipment, on the starting point of the students, on the teaching aims, etc. The teacher also foresees the way he or she will play the scene. We keep the term "affordances" for this set of characteristics that are planned before the session begins.

During the activity itself in the class, the interactions can widely modify what has been planned. When we analyse the classroom discourse, we find evidences of unpredicted suggestions by students, or unforeseen procedures (right or wrong) they use, which deviates the knowledge flow in the classroom discourse and activity, and consequently which can activate or inhibit previously organized affordances. We call *learning opportunities* the affordances that have been effectively offered to students during the classroom interactions; students can catch or not these opportunities, this is another question asking for different methodologies.

2.4. Links between the theoretical tools

These four kinds of theoretical tools are relevant with our purpose to analyse the coherence between the moments when the teacher uses ICT-based activities, and other moments of the sequence. These two kinds of activities can be at different modelling levels, on one hand, and use different types of representations on the other hand. Moreover, the term of affordance, as defined by Webb in the cited sentence, is essentially an integrated one, insisting on the various facets that constitute an affordance.

3. RESEARCH QUESTION

Taking into account the previous theoretical elements, the questions in this study are: how does the use by the teacher of an ICT-based tool construct the coherence of a teaching sequence? How does the use by the teacher of an ICT-based tool offer new learning opportunities to students, in the flow of classroom discourse?

4. METHODOLOGY

We have filmed a male physics teacher at the lower secondary school in France, during a complete teaching sequence. This sequence consists in six activities, each session lasting one hour and a half. This sequence[2] is a research-based one, as it has been elaborated in a joint group involving a researcher and several teachers.

We have indexed our video data of the entire sequence in a table (script). We identify the sessions where the teacher used the software Cabri in the sequence: two times. We have chosen to present here the analysis of a single use of Cabri (the second one, May 25).

We particularly looked at the moments when the teacher used the software, and we transcribed these moments. In the discourse of the teacher we searched all the indicators relating to the activities earlier in the sequence.

We present below (table 1) the "script" of the sequence including moments where the teacher used the software.

Date of the	Number of the activity	Learning objective indicated at the beginning of each activity	Content of the activity

[2] See the current version at http://pegase.inrp.fr/theme.php?rubrique=1&id_theme=57

session			
2010_04_06	Activity 1 Activity 2	1. Recognize the different types of lenses. 2. Understand the effects of a converging lens in terms of optics.	1. The students work in pairs to find among four lenses, which of them can serve as a magnifying glass. The strategy consists in looking through the lenses. 2. The teacher introduces the terms *diverging* and *converging* lenses.
2010_05_11	Cabri (addition)		*Modelling a converging/diverging beam of light after passing through a converging/diverging lens.*
	Activity 3	3. Show that the energy is concentrated at the focus of the converging lens for sources situated at the infinite.	3. The students carry out experiments using a thermometer, a converging lens, a screen and a lamp. Students place the lamp as a light source followed by a converging lens. They measure the temperature of the light spot formed on a screen as they move it from the lens.
2010_05_18	Activity 4 Activity 5	4. Show that some specified condition is necessary to obtain an image . 5. Understand the vision mechanism from the point of view of optics.	4. The students send the light of the lamp on a slide with the letter P. The light passes through a fixed converging lens. Students move the screen (backwards and forwards from the lens) to obtain an image. 5. The students establish the correspondence between the terms mentioned in the drawing of the eye (figure 1) and the following words in the text: diaphragm, converging lens and screen.
2010_05-25	**Cabri (addition)**		*Correspondence between the elements of the eye in a schema and a drawing.* *Convergence of the rays passing through a lens when they come from an object at a finite distance or an infinite one.* *Explanation of the accommodation phenomenon.*
	Activity 6	6. The corrective lenses for the eye defects.	6. Correction of eye defects.

Table 1: Script of the sequence titled "lens" (grade 8). The use of Cabri-files that has been analysed took place on May 25 (bold characters).

It was not planned to use Cabri-Géomètre in the sequence. That is why we have not completed the learning objective on the corresponding lines. The teacher was proposed to use Cabri files in this sequence by one of the authors, as they may facilitate the understanding of the modelling processes by the students.

5. ANALYSIS

We present the results of analysis according to each theoretical framework.

5.1. Analysis in terms of modelling processes

5.1.a. <u>Analysis of the files realised under Cabri Geomètre</u>

Cabri was used to model the convergence of light rays after passing through a converging lens. On this file, the teacher has the possibility to choose and modify the location of the object (finite distance, infinite distance) from the lens.

These Cabri files obey to the laws of Optics, and the representation obtained by Cabri refer to the world of theories / models.

Nevertheless there is a difference between the kind of representation adopted by the Cabri-files and the conventional representational rules of Optics: in Cabri-files rays are represented by lines without arrows, when optical rays carry arrows to indicate the direction of light propagation.

5.1.b. <u>Teacher's discourse analysis during the session</u>

The teacher's discourse allows us hypothesising that the teacher aimed at making a link between the two worlds. We base this interpretation on the observed identification of some elements of the world of objects and events (the crystalline lens, the pupil, the retina, all specified by the "drawing", figure 1) to corresponding elements of the world of theories and models: the lens, the opening in the square, the screen on the bottom of the square (figure 2).

In his discourse, the teacher tried to explain a phenomenon of everyday life (the accommodation) through a physical model. He suggested the situation belonging to the world of objects / events for students ("*Probably you noticed it when you are reading your textbook or a book, and you look at suddenly something far from you*") and then produced his explanation.

	Figure 1: static representation of an eye.	Figure 2: dynamic representation of an eye, from a physics point of view; representation obtained by Cabri software; case of an object at an infinite distance from the eye.

5.2. Analysis in terms of semiotic registers

The teacher made explicit for students the difference between two semiotic registers: the graphic representation and the drawing (saying for example: *you see here is a schema, it is a schematic representation, not a drawing like what we saw last week*). Nevertheless this distinction is limited because these two kinds of representation were not present simultaneously.

Through his gestures when projecting the Cabri figure, the teacher has provided links between two semiotic registers: the schematic register and the register of natural language. In fact, the teacher pointed with his finger relevant elements on the representation; for the converging lens for example he said: "*light rays as they pass through the lens as they are all converging lens* ...." (figures 2 and 3).

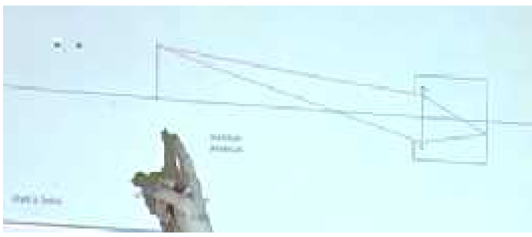

Figure 3: dynamic representation of an eye, from a physics point of view (representation obtained by Cabri software; case of an object at a finite distance from the eye).

5.3. Analysis in terms of learning opportunity

Using Cabri-géomètre, the teacher introduced a temporality to explain the convergence of a light beam after passing through a converging lens. The convergence of light may appear to be stationary (stable) when students carried out an experiment with a light and a converging lens. The use of Cabri by the teacher allows students observing the phenomenon in two phases: the light rays before crossing the lens (first phase) and the light rays after passing through the lens (second phase).
The use of a Cabri file offers to students the opportunity to visualise, for the first time, the modelling of the image obtained by a convergent lens in the case of an object at a finite distance from the lens (figure 3). The teacher gave here a new learning opportunity to students, characterised by the fact that the image is formed on the retina of the eye, whatever can be the place of the object relatively to the lens.

5.4. Analysis in terms of coherence

At many occasions during these five minutes, the teacher refered to the previous activities performed the week before by students ("*you remember*"): he recalled the experiment showing that the image through a converging lens is located in a special place behind the lens (fourth activity); but he also indicated that the situation is different for the image formation on the retina (the screen does not move), and that is his way to introduce the changes in the focal length of the crystalline, the accommodation phenomenon. Moreover he made the parallelism between the fifth activity (the schema of the eye) and the modelling of an eye in the Cabri-environment.

6. CONCLUSION

In this episode, we can observe that the meaningful articulation between the semiotic registers, the modelling levels, the activities of the sequence, allowed to this experimented teacher offering new learning opportunities to students (such as the link between their everyday life experience and the accommodation phenomenon), and strengthening the learning opportunities which had been offered in the previous sessions (like the fact that the optical image is formed in a located area behind the lens).

AKNOWLEDGEMENT

We wish to express our gratitude to the teacher who agreed to be recorded, and to the researcher (Karine Robinault) who has facilitated our access to the experimental field.

SCIENCE TEACHERS' INITIAL MOTIVATION FOR DISTANCE EDUCATION

Paulo Sérgio Garcia[1], *Nelio Bizzo*[2]
[12]Faculty of Education - University of São Paulo - Brazil – Graduate Studies in Education Program

Abstract: The science teachers play an important role in the quality of science education, and in the reforms' implementation, consequently to expand programs on teacher's continuing education is essential. As from 1996, the Brazilian Law of Guidelines and Basis of Education regulated distance education (DE), and public universities could then offer distance continuing education (DCE), broadening their role in Education. This research aims to expand understanding on factors attracting science teachers to DCE. Data were collected through interviews and questionnaires (Likert scale) with 75 participants, mainly from elementary school (80%), who took a DCE course in 2008. The results were analyzed quantitatively and qualitatively and showed a heterogeneous profile with science teachers from both sexes, wide age range, and with different experiences in distance education. The initial triggering reasons to take a DCE ranged from personal, professional, and convenience. Despite some balance among all the triggering reasons, professional ones had more influence. The DCE theme, its content relevance, and flexible schedules, were also important considerations among all others identified. These results provide public universities some elements to attract science teachers to DCE programs and to support optimal execution, contributing to the improvement of science education.

Keywords: Motivation. Distance continuing education. Science teachers.

INTRODUCTION

Teacher plays a central role in the reforms implementation (Adams & Tillotson, 1995), as well as in the quality of science education, therefore expanding programs on teachers' continuing education is crucial to improve science education (Cunha and Krasilchik, 2000).

In Brazil, several reasons make the importance of science continuing education even more acute, such as deficiencies in pre-service education (Carvalho and Gil-Perez, 2000), inadequate legislation (Garcia, Bizzo and Malacarne, 2009), and the precarious conditions of teaching (Franch, 1995).

As from 1996, the Brazilian Law of Guidelines and Basis of Education (LDBEN/96) have regulated distance education, enabling public universities (Article 80 and 87) to use innovative approaches for science continuing education.

To create attractive DCE programs for science teachers, building a deep understanding on reasons that triggers adults to enroll in such courses should be a matter of research. Rurato, Golveia and Golveia (2007b) had already proposed a transversal approach to understand the characteristics and students' motivations, because these data can provide a set of elements that can be available to construct learning strategies for students to succeed.

Although an important subject of research, the science teachers' motivation to seek DCE programs is methodologically challenging to identify and measure in a systematic approach. Several authors have explored the reasons for adults to seek DCE. Fiuza (2002) suggested a slight predominance of personal over professional ones; O'Lawrence (2007) argues that distance education' schedule flexibility enables an optimal life-work balance and was an important factor driving decisions to seek DCE; Moore and Kearsley (2007) demonstrated that improving skills for an optimal employment was the main factor. Our group has demonstrated that professional reasons play a central role in the teachers' initial motivation, specifically for science teachers (Garcia, Bizzo, Lemos, 2008).

What are the main reasons driving science teachers (or even preventing them) to seek DCE? Do personal reasons play a central role or seeking professional advancement in the career is more important? Understanding this will drive decision making to support optimal policies aiming to improve science education.

Most studies up to now do not separate reasons among sub-groups within the main study population. Do aspects such as gender, science background, age, and experience play an important role in the reasons to seek DCE?

This study aims to identify the reasons that attract science teachers to DCE. Also, this study aims to understand the impact of the teacher's profile (gender, age, education, teaching experience, and DE experience) on those reasons.

The results are relevant to universities that are interested in expanding their roles in relation to our society in general and to science education in particular. The data are also important for the construction of new distance education courses improving teacher education, and consequently the Science Teaching.

DISTANCE EDUCATION IN BRAZIL

Distance education can provide the necessary conditions for the expansion of continuing education programs. The last LDBEN/96 (Article 80 and 87) and some decrees (n. 5622, published in 20 December 2005, revoking the previous two (n. 2494 and n. 2561) regulated distance education, enabling public universities to expand their roles in relation to education and society.

The Higher Education Census of 2009 showed an advancement of distance education in Brazil. Of all enrolment held in 2009 14.1% were in this modality of teaching. There was a large increase in the number of graduates in graduate courses. In 2002 there were 133.000 graduates, and in 2009 they were already 241. 000 studying in distance education.

The Ministry of Education implemented a series of policies for the expansion of distance education. We emphasize, among others, the creation of the Department of Distance Education (SEED) and the System Open University of Brazil.

Motivation and teachers' profile

Palloff and Pratt (2003) suggest that the successful virtual student consist of working, mature people who are trying to better their opportunities, self-learners who can conduct their study schedule without having teacher to charge them, they know how to ask questions, exchange information and develop ideas.

On the other hand, Ferreira and Mendonça (2007) state, for example, that women consider the DE as a good alternative for education, because they have daily work and duties of home.

Understand science teacher profile who seeks the distance continuing education, their characteristics may help professors and tutors create new pedagogical activities. However, this profile will be better understood if it is related to other characteristics like motivation for seeking distance continuing education.

Motivation is an inner process that triggers, maintains and directs behavior. It is a psychological state, a driving force by which humans act achieving their goals (CAMPOS, 1989).

The motivation topic has promoted investigations from researchers from different disciplines. Characterized as an internal component of a person, motivation is fundamental for understanding attitudes, behavior, learning, performance, and the participation in distance continuing education.

Because motivation is not a directly observable phenomenon, it is investigated by studying people behavior in order to identify and understand the reasons underlying their inclinations and actions. Murray (1986) states that although there are multiple visions and conceptions of motivation there is a consensus that is the reason, such as internal factor, which initiates, conducts, maintains, and integrates a person's behavior.

The reasons, according to Hersey and Blanchard (1986), are synonymous of desires, instincts, impulses, needs and interests of the person. Motivation is related to the intensity of these reasons. For Lima (2000) one reason is a construct that can not be observed, and is constructed by the person to explain why he or she has the need to act in this or that way to perform an action. Thus, both the strength of each reason and the standard of them have an impact on how the person understands and interacts with the world around him.

Adults have a variety of reasons to learn and to make choices about learning. In the United States, Moore and Kearsley (2007, p. 174-175), state that students have as initial reasons for enrolling in distance education courses the compliance with university credits, the search for new knowledge, personal investment, the attempt to improve the income and employability.

Fiuza (2002), in a study of motivational aspects related to distance education in a master's degree distance course, listed a set of motivating factors (reasons) that lead workers to seek the distance education. The author has grouped the frequency of student responses showing a slight predominance on the personal aspects over professional ones. In another study, over a distance course of specialization, Gomez (2000) showed that participants were motivated to pursue the distance course by professional, personal and practical reasons.

O'Lawrence (2007) in his article "An Overview of the Influence of Distance Learning on Adult Learners" reveals, on one hand, that adults participate in distance education programs to enhance their skills, by the pressure of having to earn a diploma and because the incentives they receive from their employers. On the other, the author identified other issues such as lack of time, transport issues, optimal life-work balance, and flexibility of the course.

In a study in 2008, studying science teachers in a distance continuing education our group found that professional reasons play a central role in the teachers' initial motivation (Garcia; Bizzo; Lemos, 2008). Although in this study we only grouped the reasons (the frequency of student responses) that motivate science teachers to seek distance education.

METHODS

This study aims to identify the reasons that attract science teachers to DCE. Also, this study aims to understand the impact of the teacher's profile (gender, age, education, teaching experience, and DE experience) on those reasons.

With this goal in mind, our group decided to select a DCE science course applied by a public university for free. After identifying the study population, a sample of the teachers was selected to be interviewed (N=12) and results from those interviews were used to prepare a questionnaire. After the initial validation of the questionnaire with a pilot study (performed with 11 other teachers from the same study population), all teachers (N=138) received the final version of the questionnaire. Data collected from the returned questionnaires was compared and contrasted to achieve the study goals previously described.

The questionnaire consisted of open-ended questions and one Likert scale. We collected data on the participant profile: gender; age; academic background, graduate degree (yes/no), teaching experience (in years), and distance education exposure (yes/no). As to initial motivation for choosing this type of DCE we used a Likert scale with 27 items.

The raw data from the returned questionnaires (75 out of 138 participants) was analyzed forming three main groups of latent variables called domains (personal reasons, professional reasons, and convenience reasons). The consistency of three latent variables was checked using Alpha of Cromback, showing levels higher than 60% (according to Pestana and Grangeiro, (2005) it is acceptable to social science one alpha > 0,6).

Data were analyzed using the Statistical Package for Social Sciences (SPSS 16.0 for Windows) and "R" (http://www.r-project.org). To compare the domains related to gender, graduate degree, previous exposure to DE, nonparametric tests (Mann-Whitney test) were used. To compare the teaching experience and the three main domains, the Kruskal-Wallis was used. The correlation between age and each of the domains' variables was analyzed using "p" Spearman. To determine which domain had the greatest impact on the science teachers' initial motivation, Friedman' test was used. For all comparisons, we adopted a significance level $\alpha = 0.05$.

RESULTS AND DISCUSSION

The selected course was performed annually by Sao Paulo University. Data was collected from the 2008 class. The course theme was "Nutritional Education: the food label in the classroom of elementary science education". The objective was to update science teachers in nutrition. The course had 60 hours performed over two months, with 58 hours of distance education and two hours final test (in person). From the 138 questionnaires submitted, 75 answered questionnaires were returned.

Results from the answered questionnaires showed teachers from different regions: South, Southeast, Midwest and Northeast. They were mostly women (80%) with an average age of approximately 33 years. Fifty-eight percent majored in Biology with a graduate degree (52%). Nearly 54% (53.3%) worked in a state public school, 78,3% in elementary school, 55.9% had more than five years of teaching experience, and 52% did not have any experience in DE.

The science teachers' initial motivation (reasons) to participate on the course varied widely. The higher scoring items are described below (table 1).

Table 1 – Science teachers' initial motivation (reasons) – 2008

	Statement	Mean	SD
MI03	**Interest on the course topic for my classes**	**3,84**	**,436**
MI10	**Improve my professional knowledge on the topic**	**3,71**	**,653**
MI11	**Use professionally the acquired knowledge on my students**	**3,50**	**1,113**
MI21	**Flexible schedules**	**3,35**	**1,020**
MI15	**The fact that the course could improve the quality of my classes**	**3,31**	**1,185**
MI25	**The possibility of reconcile work and continuing education**	**3,28**	**1,008**

MI24	**Opportunity at the time the course was open**	**3,27**	**1,031**
MI23	**Technology, tools available (to attend the course)**	**3,24**	**,867**
MI06	**Because the course was free**	**3,22**	**1,264**
MI26	**The possibility of reconciling family life and work**	**3,11**	**1,169**
MI08	**Interest in information to improve my personal nutrition**	**3,05**	**1,038**
MI01	**Interest in taking a distance course in Nutrition Education**	**3,03**	**1,273**

Among the most mentioned items, three were in the personal domain (MI01, MI06 and MI08), four to the professional (MI03, MI10, MI11, MI15) and five to the convenience (MI21, MI23, MI24, MI25, MI26). These reasons were the most important and influenced science teacher's decision to seek a DCE.

In the analysis of the interface between domains and variables (sex, age, graduate degree, teaching experience, and previous exposure to distance education), it was noted that all three domains were important influencers of the decision making to take a DCE. However, when teachers had higher levels of education (graduate degree, p=0.014) or with longer teaching experience (p=0.013), the professional domain had a more impact. Other analyzes yielded no statistically significant differences.

The test applied to analyze the correlation between each of the three domains showed that the professional domain (Median=3,00) was the most relevant to the science teacher's decision making.

SOME IMPLICATIONS

Data described previously listed the reasons to attract adults to distance education (Fiuza, 2002; O'Lawrence, 2007; Moore and Kearsley, 2007). The results presented here further expand the understanding on the science teachers' initial motivation to take a DCE course. Furthermore, explore how the teacher profile (gender; age; academic background, graduate degree, teaching experience, and distance education exposure) impact on the motivation to take a DCE course.

Rurato, Golveia and Golveia (2007b), in a study on the characteristics of students in distance education and the motivating factors, proposed a transversal approach to know the characteristics and motivations of students. According to these authors, these data can provide a set of possible elements helping professors to construct learning strategies for students to be successful. However, our results suggest more than a simple cross-cutting approach to know the characteristics and motivations of science teachers. They point to the need to explore the science teachers' profile attracted to the DCE and connect it to the initial motivation.

The implications of those conclusions bring the need to ensure a deep understanding of several aspects of the DCE to design an optimal course. In those three domains is required a combination of the theme, current and relevant, the relevance of knowledge, current, contextualized with links to teacher personal and teacher professional life, and schedule flexibility enabling an optimal life-work balance

Also it is relevant to shape courses differently to specific subgroups of teachers according their initial motivations. Those science teachers with higher levels of education or with longer teaching experience, who were attracted by professional reasons, and the others, who were attracted by personal or convenience reasons, need to have their interests assisted in different pedagogic perspectives.

Finally, we stress that these results are important to universities. Public universities can expand their roles in relation to our society in general and to science education in particular.

They have enough information to attract science teachers to DCE programs and for the construction of new DCE courses improving teacher education, and consequently the science education.

Abstract: This research investigates the use of Assistive Technologies (AT) in the process of inclusion of a visually impaired pupil based on different actions involving the teaching of Sciences, the school community and the family. A qualitative research approach was used, and a case study framework was adopted. The field of study was a state school in the city of Boa Vista, Roraima, Brazil, which accepts people with special needs in regular groups of the elementary school years. The object was the teaching of Sciences. The subject was a blind student with Delleman Syndrome who has undergone 21 surgeries. The subject uses AT as resource to assist in school attendance, in the personal development process and in the construction of knowledge and learning since early education. Interviews on the object of study were also conducted with teachers of Sciences in ordinary groups with special pupils and teachers working in teaching rooms equipped with visual resources. This approach afforded to understand the reality being investigated.

Keywords: School Inclusion; Assistive Technologies; Pedagogical Practices for the Teaching of Sciences.

INTRODUCTION

In Brazil, the National Policy for Special Education in the Perspective of Inclusive Education established the right to education to all children with special educational needs. In this sense, one of the focal points of this policy is regular teaching practices in conjunction with specialized educational service, which has to be offered before or after the respective daily school shift. Programs to enrich curricula, language teaching and specific communication and signaling codes also have to be included, apart from Assistive Technologies (AT).

1. THE TEACHING OF SCIENCES IN THE SPECIAL EDUCATION CONTEXT

The need to promote and develop the teaching of Sciences lies in the fact that these variables afford the student to better follow the evolution of science as well as the transformations that take place in nature and in human history. In this context, apart from being informative, the teaching of Sciences may also endorse scientific reasoning.

With this objective in mind, the Ministry of Education (MEC) implemented the National Curriculum Parameters (PCN) and, in the context of Special Education, adopted a set of guidelines titled "Curriculum Adaptations of National Curriculum Parameters in the Teaching of Pupils with Special Needs" (BRASIL, 1998).

The teaching of Sciences to visually impaired pupils demands from the teacher more than the development and application of activities focused on the content to be taught. Ironically, the persistence of a methodological and conceptual link observed between these teaching contents and visual didactic and pedagogic models adopted in scientific theories makes it more difficult for the teacher to bridge the didactic transposition as expected (CAMARGO *et al*., 2006).

Another aspect that deserves to be stressed is the fact that Assistive Technologies may be used as interfaces in the learning process, which leads to more intense interaction and independence of the blind pupil in the classroom environment, promoting learning skills.

2. The pedagogical practice in Sciences: the data obtained

This study relied on the cooperation of eight teachers of an elementary school in the State of Roraima, Brazil. Based on the roles each teacher performed, they were identified as follows: two Sciences teachers (P1 and P2), one educational advisor (P3), the school's principal (P4), one classroom teacher (P5) and three visual resources teachers (P6, P7 and P8). The subject assessed in the present study was a 17-year-old 6th grade junior high pupil called R., who has oculocerebrocutaneous syndrome (OCCS), also called Delleman Syndrome. This disease is a multiple syndrome of congenital anomalies characterized by orbital cysts, brain malformation, congenital cleft upper lip and palate, neurosensory deafness and focal dermal hypoplasia. However, the subject who participated in this study did not present brain malformation (BRANDÃO, 2010).

The periods the teachers who took part in this research were working with blind pupils varied between 1 and 10 years, mean 4.25 years. Concerning specialized teacher training, five teachers declared having no specialized education in teaching blind pupils, three informed that they had taken a specialization course for teaching special pupils, and these same teachers said that had taken a further education course and/or participated in occasional training programs to meet the needs of blind pupils.

In terms of the knowledge of the Braille system, the two Sciences teachers said that they did not know the system and that only the teachers assigned to visual resources activities had specific training for that purpose. The same was observed concerning the teachers assigned to pedagogical tasks in the school.

When analyzing the pedagogical practices carried out by teachers and how ATs are used by R. in Sciences classes in terms of accessibility, inclusion, formation, as well as the knowledge and the perceptions the teachers have about these technologies and their notions concerning teaching and learning using ATs in the case of a disabled subject, we observed that:

- The views about teaching, learning and visual impairment vary considerably among the members of the study group, from a transmission-reception approach to a view based on the interaction between teacher and pupil.

- Considering the teaching process that resorts to ATs, only the visual resources teachers understand that the teaching process is not restricted to the classroom and the blackboard. For these teachers, "there is no single way to teach; everything depends on the pupil's needs" and "the creativity of individual teachers is very important".

- Considering the learning process, the teachers did not identify the difference between the use of ATs and the blackboard. The didactic strategies and/or tools they utilize in the classroom so as to facilitate the learning by a blind pupil in Sciences classes are the "blackboard", "speaking louder, nearer to the pupil so as to afford him to listen in better", "dictations of the activities for the pupil to copy". However, both stress the fact that the visual resources classroom is the site that has the technological and didactic resources that facilitate the learning by blind pupils.

- Three teachers answered directly that the technological and didactic resources that facilitate learning are located in the visual resources classroom. One of these teachers stresses the fact that these "are essential resources in the learning process", mentioning "the importance of the slate and of the stylus, since the blind pupil is unable to write without these instruments". Also, it was said that "the use of the Braille System is the first step for the inclusion of a blind pupil". Three teachers did not answer the questions about learning.

- The words of the Sciences teachers afforded to observe that they use the visual resources classroom as the only technological tool, since "it is the place where capacitated professionals are available to direct pupils in their extra-class or complementary classroom activities".

The techniques and strategies used by teachers of Sciences evaluated here are still based on expository classes. When planning the activities in a classroom with visually impaired pupils, it is the teacher's duty to offer the pupil the conditions and opportunities to explore his/her own intellectual skills, promoting a multi-sensory learning process (SILVA, 2006).

Concerning the pedagogical practices in the classroom that aim at the pupil/teacher and teacher/pupil interaction, teachers P1 and P2 underline the importance of classes based on traditional methodologies, as in the "blackboard", as well as of the sporadic group work and of Sciences lab classes. In R.'s own words, "In the Sciences lab she allowed me to grab things so as to better perceive them".

When commenting on the didactic strategies and/or resources used in the classroom to facilitate the learning of Sciences, P7 says, "The material is adapted as requested by the teacher and he would very properly say that that material was not good for him and that it needed adaptation".

The interviews with the teachers and the *in loco* observation carried out during the two years (2008 and 2009) R. was assessed prove that the subject did not feel difficulties to follow scientific reasoning and that he was very skilful in writing the classroom exercises in the Perkins device.

3. Conclusion

The analysis of the data collected in the school investigated indicate the rather limited understanding teachers have of the inclusion of special educational needs, ATs, and didactic resources for the blind and visually impaired. According to these teachers, considering R., learning and teaching using ATs (inclusion) takes place in the visual resource classroom.

The data collected and analyzed afford to observe the considerable limitations around the understanding of school inclusion, inclusion of pupils with special education needs, AT and didactic resources for the blind and those with visual impairment, from teachers P1, P2, P3 and P4, in the school where this research was conducted, in the state of Roraima, Brazil. In the opinion of these teachers, more specifically concerning the pupil R., teaching and learning using ATs (inclusion) take place in the visual resources classroom. However, P6 and P7, who are assigned to the classroom mentioned, understand that teaching and learning do not depend on the physical space as such, and that these activities are indeed influenced by the needs of a given pupil.

In this sense, the teaching of Sciences using these technologies, more specifically for R., and ATs, may add to supporting issues of didactic/pedagogical character more directly related to everyday school activities. Additionally, these technologies may enable the conditions to understand how the pupil with visual impairment interacts with reality, effectively developing his own learning processes.

Finally, the use of ATs in the teaching of Sciences not only facilitates accessibility and social inclusion of visually impaired subjects, but also promotes the teaching and learning of the subject, affording the pupil the tools to search for information he or she needs and (re)constructing his or her own knowledge.

PRESCHOOL SCIENCE EDUCATION WITH THE USE OF ICT: A CASE STUDY

Michail Kalogiannakis[1] *and Nicholas Zaranis*[2]

[1]Lecturer, University of Crete, Department of Preschool Education, mkalogian@edc.uoc.gr
[2]Assistant Professor, University of Crete, Department of Preschool Education, nzaranis@edc.uoc.gr

Abstract: In recent years we have become increasingly aware of the need for people to understand the nature of science in order to make decisions posed by new developments in both science and technology. This case study is part of a wider research project concerning the use of Information and Communication Technologies (ICT) for teaching main natural science's concepts and mathematics in early year's classroom. The study was conducted during 2010-2011 school year and 270 pupils were participated. The integration of ICT into preschool education has become a high priority for everybody involved in the learning process. The Early Numeracy Test was given to pupils and semi-structured interviews with young children were conducted in 18 preschool classes in Crete. Pupils in the control group received only the traditional science instruction about natural sciences (solubility, recycling) and mathematical concepts (comparison, classification and general knowledge of numbers). Pupils in the experimental group received only the science instruction with the use of ICT for the same topics. Both the experimental and the control groups consisted of classes from the same participating schools. The incorporation of ICT in early year's classes in Greece should be considered as a means of an obligatory modernization of learning and teaching methods. The results of our research showed that teaching and learning through ICT as an innovative teaching method can be successful for understanding the concept of numbers and natural sciences phenomena at preschool level.

Keywords: Preschool Education, Mathematics, Solubility, Recycling, ICT.

INTRODUCTION

Science, apart from representations of the world, also involves ways of intervening in the world by putting things to work in the laboratory according to theories and models. Scientific literacy, the goal of science education, involves conceptual knowledge, problem-solving strategies, understanding the nature of science, and an appreciation of the interaction between science and society (Stohr-Hunt, 1996).

Science education at the preschool level with the use of ICT (Information and Communication Technologies) that emphasizes active learning, may be expected to promote higher student motivation than what occurs in traditional classroom settings with teacher oriented learning. Numbers and natural phenomena invoke the interest of children from a very young age (Geary, 1994; Bryant 1997; Chen, 2009). Our research reveals ICT uses in Greek preschool education and explores this use of ICT for science education.

THEORETICAL FRAMEWORK

During the last 10 to 20 years European countries have had problems engaging students in science (Osborne & Dillon, 2008). Children construct their knowledge of the world on the basis of two information sources-observations of the world and explanations given by other people (Vosniadou, 2002; Kikas, 2003).

Scientific concepts may be hard to grasp even by adults; however, this does not mean that children cannot think abstractly about scientific concepts. On the contrary, literature shows that children are able to think about even complex concepts (Zimmerman, 2000). Learning theories now accept the importance of learning processes at this age and, moreover, research studies have provided strong evidence that appropriate teaching interventions can help pre-school children accept basic scientific ideas concerning common phenomena of the natural world (Ravanis, 1994).

Pupils’ responses to events involving changes of state and dissolving have been studied in a variety of contexts over the past two decades. For Slone and Bokhurst (1992) the child is be able to consider both variables, the sugar and water, simultaneously (dependent on preservation), must understand direct and inverse relations (dependent on liquefaction or atomism), and must have the ability to assign numbers to the amounts of sugar and water and to compare the ratios. According to Prieto, Blanco and Rodriquez (1989), ideas held by 11 to 14-year-old Spanish students about solutions and the process of dissolution attach a good deal of importance to the mechanical actions and manipulations involved in dissolving the substances (e.g., stirring, shaking, heating, etc.). Lee et al. (1993) have reported about 50% of a sample of 11 year olds demonstrating an understanding of particle explanations for states, change of state, expansion and dissolving. For Papageorgiou and Johnson (2005) particle ideas helped with the development of 10/11 years old pupils’ understanding of phenomena of changes of state and mixing.

In addition environmental education is recognized as an educational process that significantly promotes all aspects of an overall and balanced personal development of young children, in the psychological, emotional, cognitive, social and psychomotor sectors (Flogaitis, Daskolia & Liarakou, 2005). However, although the significance of environmental education in early childhood education has been recognized early on internationally (Tilbury, 1994) and efforts have been made for its inclusion in kindergarten schools, research in the field remains largely limited. Despite the fact that environmental education’s general conceptual and methodological framework is widely accepted by the Greek educational community, the matter of its interpretation by national educational policy-makers and the approaches they promote for the application of environmental education at each educational level remains open (Flogaitis, et al., 2005).

The adequate preparation of teachers at all school levels in environmental education is considered, even today, to be lacking. The main emphasis has been primarily placed on the in-service training of teachers with the thought that most practitioners have not received any relevant pre-service training in environmental education (Flogaitis, et al, 2005).

A vast number of studies relate the appropriate use of computers with the ability of students to understand more efficiently the different mathematical notions (Dunham & Dick, 1994; Groves, 1994). Thus, it becomes obvious that kindergarten emerges as a very attractive environment of investigating the computer use in mathematics education. Indeed, various research results show a positive interrelation between the use of computer and the development of mathematical thinking in kindergarten (Clements, 2002; Clements & Sarama, 2004).

We consider it necessary to think of planning various activities related to science and technology, so that preschoolers would broaden their field of experiences and construct certain primary representations, which would later on form the background to build up scientific concepts (Solomonidou & Kakana, 2000). Science education at preschool level with the use of ICT that emphasize active learning, may be expected to promote higher students motivation than occurs in traditional classroom settings with teacher-directed learning.

ICT use has been applied experimentally at the preschool level on a wide scope of skills and knowledge acquisition. Results demonstrated a significant contribution of ICT use in the classroom as a learning tool (Clements & Nastasi, 1992; Clements & Sarama 2003; Vernadakis et al., 2005). It is well known that children learn faster in an interactively functioning learning environment. This is probably the most important advantage of ICT use in the teaching process against traditional teaching. Moreover, the use of computers as a teaching tool allows children to learn at their own individual pace (Zaranis & Oikonomidis, 2009). Upon achieving one level of knowledge they can proceed to the next, which is not the case in traditional teaching.

Generally speaking, in order to maximize the benefits of ICT use in education, all the educators should keep in their minds this question: 'Can we use technology to teach the same old stuff in the same way or can we capitalize on the benefits of technology by using integrated computer activities to increase achievement? (Clements & Sarama, 2002).

METHODOLOGY

Our research study uses Early Numeracy Test (ENT) (Schopman et al., 1996; Aunio et al., 2004) and audio-recorded semi-structured interviews about solubility and recycling to explore the use of ICT in preschool classroom for teaching basic mathematical and natural sciences concepts. The ENT is a task orientated test which attends to measure the level of early mathematical competence. The test has been developed for kindergarten and consisted of forty items. The ENT consisted of eight parts and the tasks were spread over these parts in group of five. The ENT was examined individually. The components of the ENT where our study focused were: concepts of comparison, classification and general knowledge of numbers.

The semi-structured interviews focused especially on: solubility and recycling. The following questions were examples of what we asked the students: Does lentils, beans, chickpeas, rice, sugar, salt, pepper, and, coffee dissolved in water? What do you think when you hear the word recycle? What is recycling? Recycled camera? Recycled food cans, plastic bottles, stones? What is it made with the scissors, books, and bottles? Which buckets dump the plastic bottles, newspaper, and metal teapot? Recycled food? Draw a trashcan and a material that we throw into it when you do not need it anymore.

The study was conducted during 2010-2011 school year and 270 pupils were participated. The Early Numeracy Test and audio-recorded semi-structured interviews were conducted one-to-one in private and were given to children, aged from 4 to 6 years randomly selected, in 18 preschool classes in Crete (Greece). It took about half an hour for each interview or test and they were given to the children as a pre-test and post-test before and after the teaching intervention. There were two groups in the study, one control and one experimental. In the control group there was not a computer available for pupils' use, while in the experimental there was one. The research study was conducted from November 2010 to April 2011.

Pupils in the experimental group received only the science instruction with the use of ICT for the same natural sciences phenomena and mathematical concepts. Both the experimental and the control groups consisted of classes from the same participating schools.

The teaching process for both groups consisted of four weekly syllabus. The control group coordinated with traditional teaching. That included a story about the three little pigs that had three bags with sugar, beans and salt and passed through a great river. Another story was of recyclable materials, bottles, cans and paper that were neglected at the beach and they were very sad because they had been used and felt useless, until one day the newspaper brought the good news of recycling. Group and individual activities were given to children every day in order to understand what materials were recycled in the yellow bin, which the green and what in the blue bin. In addition they did experiments in which dissolved in water, various materials as sugar, salt, beans, chickpeas, lentils, coffee, etc. Moreover, there were quizzes given periodically and procedures were given at the conclusion of each number form one to ten.

The experimental group covered the same material at roughly the same time, but spent one class hour per week with the computer. The software was designed using the Flash CS3 professional environment and consisted of six distinctive counting activities for numbers from one to ten. Each one of them implicated pupils into different aspects of counting situations. More accurately, pupils were asked to reach solutions to problems, in which counting played an integral role. The computer activities were selected according to the kindergartens' curriculum and complements what children had been previously taught in class. The general environment of the software could be described as open ended, which allows pupils freedom of use and navigation, although there were some drill and practice features as well. Concerning the natural sciences phenomena the teaching intervention of experimental group used software which included stories and activities about solubility and recycling.

The role of the main teachers and student teachers were to be facilitators to help children solved any problems, but only when children really needed help. The data analysis from the tests was carried out using SPSS (ver.19.0).

RESULTS

The ENT and interviews were taken by 270 pupils. One hundred and thirty one of the pupils were male and one hundred and thirty nine were female. Data analysis was done by the SPSS statistical analysis program. Independent samples and paired samples t-test were carried out. The independent variable had two categories the experimental group (132 children) and the control group (138 children). The dependent variable was the total pupil's score from the semi-structured interviews about natural sciences phenomena (solubility and recycling) and mathematical concepts (comparison, classification and general knowledge of numbers).

The t-test for equality of means was not significant ($t = -0.684$, $p = 0.495$), indicating no significant differences initially, in numeracy and natural achievements between the experimental and control groups. Though the experimental group had a mean score ($m=25.822$) slightly higher than the control group ($m=25.517$), the mean difference was less than -0.300. The results of this pre-test are summarized below (Table 1):

Table 1: Independent Samples Test of pre-test

	t	df	mean difference	Sig. (2-tailed)
PRE-TEST	-0.684	206	-0.300	0.495

In order to determine if the performance of the experimental group was significant, a paired t-test was performed using the grades of this group for a comparison between pre-test and post-test of the scores. The mean grade for the pre-test of the study was 25.82 (SD= 4.39) compared to 35.35 (SD= 2.41) of the post-test. At $\alpha = .05$ and df = 131, the critical value of the t ratio was less than 0.001 (Table 2). Therefore, the post-test score was significantly different from the pre-test score in the experimental group.

Table 2: Paired Samples Test of pre and post tests in the experimental groups

	t	df	Mean	Sig. (2-tailed)
Pair 1 pre-test- post-test	-29.036	131	-9.530	0.000

Similarly, to determine if the performance of control group was significant, a paired t-test was performed using the grades of this group for a comparison between pre-test and post-test of the scores. The mean grade for the pre-test in the study was 25.52 (SD=2.51) compared to 34.65 (SD=3.23) for the post-test. At $\alpha = .05$ and df=137, the critical value of the t ratio was less than 0.001 (Table 3). Therefore, the post-test score was significantly different from the pre-test score in the control group.

Table 3: Paired Samples Test of pre and post tests in the control groups

	t	df	Mean	Sig. (2-tailed)
Pair 1 pre-test- post-test ENT	-31.512	137	-9.130	0.000

Finally, an independent sample t-test was conducted. The t-test for equality of means was significant ($t = -2.007$, $p = 0.046$), indicating significant differences, in the scores between the experimental and control groups. The results of this post-test are summarized below (Table 4):

Table 4: Independent Samples Test of post-test

	t	df	mean difference	Sig. (2-tailed)
POST-TEST	-2.007	268	-0.700	0.046

Results of this study expand the research on the effects of appropriate programs embedded in a computerized environment for mathematics and natural science (Ravanis, 1994; Dunham & Dick, 1994; Groves, 1994; Solomonidou & Kakana, 2000; Clements, 2002; Clements & Sarama, 2004; Flogaitis et al., 2005).

CONCLUSIONS - DISCUSSION

Results of this study tend to confirm that ICT can be an effective method for teaching selected beginning scientific concepts and skills. Initially, there was no significant difference between the experimental and control group achievements. However, throughout the study, the experimental group had higher achievement than the control group. Despite that, both the experimental and control group had great achievements between the starting and the final level.

Using ICT appropriately with young children for science teaching is vital in early childhood settings. Pupils like use ICT mostly because it is something new compared to a traditional science lesson. Providing computers in each preschool classroom does not mean that the teacher will incorporate effectively ICT for science teaching. It is essential that early years teachers should be trained in the ability to apply ICT and to interact with the children during the learning process. Attending training programmes and keeping an open mind are the keys to a teacher's success.

This study is preliminary in its nature and is in progress. Other studies need to be designed, in order to replicate this treatment with a larger number of subjects and to attempt answering other questions that did not arise in this research.

The use of ICT in early childhood education is not a panacea and researchers ought to study more deeply the complex pedagogical issues involved in the uses of ICT. We argue that a change is necessary so as an innovative teaching method can be successful, not only concerning materials, but also concerning approaches and beliefs.

KNOWLEDGE ORGANIZATION IN UNIVERSITY PHYSICS TEXTBOOKS

Sharareh Majidi
Department of Physics, University of Helsinki
P.O. Box 64
Gustaf Hällströmin katu 2
FI-00014 University of Helsinki

Abstract: Textbooks are often the major source of knowledge in science education that provides teachers and students a conception of how scientific knowledge is organized. Therefore, it is of interest to recognize how knowledge is organized in the textbooks. In this study the knowledge organization in three introductory university physics textbooks are analyzed from the viewpoint of how concepts are structurally related. The examined subject is magnetostatics with specific topics of Biot-Savart law and Ampère's law. The method of analysis is based on the interpretative analysis and categorization, which recognizes the basic elements and basic links, which connect these elements. These basic elements and links form the skeletal structure of knowledge organization. Finally, the knowledge organization of textbooks are represented by using concept maps and classified qualitatively on the basis of their topological outlook, revealing the essential differences in their structures.

INTRODUCTION

The crucial role of textbooks on student's learning has been highlighted in many studies. For example, in National Educational Goals Panel (1998) of United States, there are some recommendations regarding the implementation of standards "Textbooks are where students meet the standards." It suggests that students and teachers should have instructional materials such as textbooks, which could help them to meet academic standards. Roseman et al (2010) analyzed the contents of four biology textbooks in order to examine their coherency. They specified the key ideas as well as other ideas within the textbooks and the alignments and connections among them. They reported that the judgments of their review team about the connections among key ideas were less consistent than the judgements about connections among key ideas and other ideas. Moreover, they noted that guidelines that were provided for making judgments about alignments were more explicit than guidelines about connections. In this research, it has been attempted to construct an explicit guideline for basic elements as well as guideline for connections (links) between basic elements.

Knowledge organization is an important component of understanding learning and teaching (Novak, 1982). diSessa (1993) argues that gaining an organized and integrated knowledge is a basis for cognitive processing (e.g. problem solving or complex reasoning). Teachers rely on textbooks in order to know how they should teach. Teachers would benefit considerably from textbooks if they are able to recognize and use such effective structures of knowledge organization in their own teaching (Ball & Cohen, 1996; Davis & Krajcik, 2005).Therefore, the in-depth understanding of the knowledge organization assists teachers to arrange their teaching materials. Similarly, understanding how knowledge organization possibly affects learning process is equally important. Knowledge organization is without doubt an important basic problem in all learning and teaching, but where do teachers and students actually get examples of those organized knowledge. For example, comparing knowledge organization of experts and novices has revealed that experts have an integrated and efficient knowledge organization with meaningfully related elements (e.g. principles and concepts) while students often have difficulties to organize their knowledge (e.g. students do not have sufficient interconnections between the pieces of their knowledge). Quite naturally, the study materials such as textbooks guide the development of knowledge organization of both teachers and students. These notions motivate to find out how knowledge organization differs in different textbooks.

THE METHOD OF ANALYSIS

The purpose of this study is to find a way to present how knowledge in a textbook is connected and what kinds of structures knowledge organization these connections form. In order to make this explicit, the following research questions were established:

1. What are the characteristics of links (forming the knowledge organization) in different textbooks?

2. What kinds of knowledge organization exist in textbooks and how these organizations are different?

The first task is to develop a framework for analysing the units forming the knowledge organization. This includes recognising the basic elements like concepts and laws in the textbooks. Then the ways of connecting these basic elements (called here the links between the basic elements) are categorized. After developing the framework, the knowledge organization in the textbooks could be presented by using concept maps based on the categorized basic elements and links. In the recognition of the basic elements, the classification of elements suggested by Koponen and Pehkonen (2010) is utilized that posited that basic elements include concepts, entities, particular laws or law-like relations and principles.

After the basic elements were recognized, the connections between the basic elements in the textbooks were examined. In order to examine these connections (links), preliminary ideas of possible categorization were formed based on the role of experiments and modelling in the construction of knowledge (Koponen & Mäntylä, 2006). From the basis of earlier studies (Koponen & Mäntylä, 2006; and references therein), a category for experiments in connecting the basic elements was one reasonable possibility. However, the experiments were not detected in the studied textbooks in the cases of Biot-Savart law and Ampère’s law. Harrison and Treagust (1998, 2000) investigated the textbooks stressing the use of models. They developed a typology of school science models to classify the textbooks’ models. Their typology consists of mathematical and theoretical models, analogical models, models depicting multiple concepts such as maps, diagrams. Van Heuvelen (1991) classified physics knowledge into four main categories: words, pictorial representation, physical representation and math representation. In his classification, models somehow help students to construct representation of physical process, reason about the process, construct mathematical representations, and finally solve physics problems qualitatively.

Before forming the knowledge organization of textbooks, the classification of elements and links were judged in order to increase the validity of the analysis. For this purpose altogether six questionnaires (two topics and three textbooks) concerning the classification of basic elements and links in textbooks were designed. Four reviewers answered the questionnaires (i.e. judged the classifications made). These four reviewers are university lecturers with Ph.D. in physics, and they have taught first year physics courses. Hence, they are experts of the chosen topics of Biot-Savart law and Ampère’s law, and they are familiar with the introductory university physics textbooks. Finally, the concept maps that depict the knowledge organization of textbooks were drawn. When drawing the overall concept map, these structure elements are put together: basic elements as nodes and the categorized connections as links between nodes. Here the application of concept maps differs from the traditional way: in a link of the map there is, instead a verb, a procedure that connects the basic elements to each other (compare with Koponen & Pehkonen, 2010). Then the features of the knowledge organizations of textbooks made visible through the concept maps were qualitatively interpreted, analyzed, and compared. Calculating mean value and standard deviation of the items of questionnaires validated the interpretation and analysis of the basic elements and links forming the knowledge organization.

RESULTS

Recognized basic elements

Considering the topics of Biot-Savart and Ampere's law, BE are identified and presented in Table 1.

Table 1. Basic elements and their types identified in three studied textbooks.

*** Common basic elements in three textbooks are indicated by Bold. Common basic elements in HRW and Knight are indicated by Italic.**

Basic elements in all of the textbooks are identical. They have eight basic elements in common (from 1 to 8 in Table 1). The textbook of FLS has less basic elements than the other two textbooks; moreover this textbook includes some advance basic elements (e.g. Vector potential, Stokes theorem, Maxwell equation). The textbooks of HRW and Knight have eleven elements in common (from 1 to 11 in Table 1).

Categorization of links

The method of analysis and categorization of links needs consistently to specify the nature of links and to show how they connect the basic elements. In examining how the basic elements were connected, the links were categorized as follows:

1. Descriptive model (DM): A mathematical model that connects basic elements through mathematical relations or equations. In general, descriptive model links basic elements with mathematical format to new laws with mathematical expressions.
2. Explanatory model (EM): A mathematical model, which links basic elements through mathematical expressions. Usually the explanatory model connects the applications or implementations of laws (with mathematical format) to the closely related laws. In contrast

to descriptive model, which describes new laws, explanatory models explain the applications and implications of the defined laws.

3. Visual model (VM): This model applies for visual perceptions. Visual model connects different basic elements through the diagrams, photos, and figures.

4. Statement of fact (SF*):* Concerns declarative knowledge. This knowledge gives information about the facts such as observations, discoveries, and phenomena.

5. Reasoning (R): A mode of presentation, which can be considered also as a model that gives reasons or arguments to justify the connections between basic elements. Reasoning might be inductive reasoning (reasons are based on the previous experiences or observations or laws) or deductive reasoning (reasons follow a set of premises).

6. Reference to previous knowledge (RPK): A model, which refers to previous knowledge. This is often done in a form of analogy.

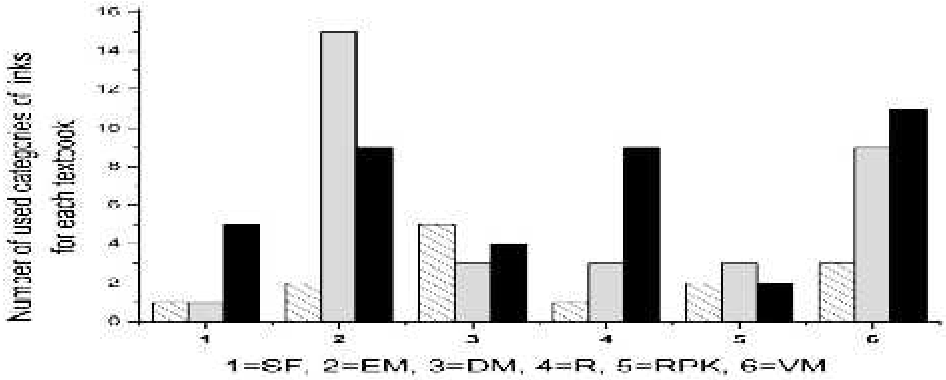

Fig 1. The number of categories of links. Used categories of links in FLS are shown by dashed bars, in HRW by gray bars and in Knight by black bars.

When comparing the total number of links, it can be seen that in FLS, there is only 14 links altogether and in Knight, there is 50 links. The HRW is between these two with the number of 34 links. Although, there is not a big difference in the number of basic elements between studied textbooks, but there is a big difference in the number of links between the textbooks (Table 1). In Fig 1, the number of links in respect to the types of links (1-6) in case of each textbook is presented in bars. It means that the tallest bar for each category (link) is the most applied link and the shortest bar is the least used link. It can be seen from the Fig 1 that in Knight (black bars) the different types of links are used in versatile ways. In FLS, the number of links (dashed bars) is low in comparison to other textbooks. In case of HRW, there is a clear emphasis on explanatory and visual models.

Representing knowledge organization of textbooks by concept maps

Since review team validated developed framework and created links, it is possible to make concept maps representing knowledge organization for each textbook. The recognized basic elements (presented in Table 1) are the concepts and connections between them are the categorized links (see last section). The concept maps are tried to construct in hierarchical fashion, where the hierarchical structure of a specific domain of knowledge depends on the context in which the knowledge is applied. The concept maps here include also cross-links, which connect different domains or segments of knowledge. The concept maps here differ in relation to the most prevalent way of constructing concept maps in one way: instead of propositions, the links are the categorized modelling procedures.

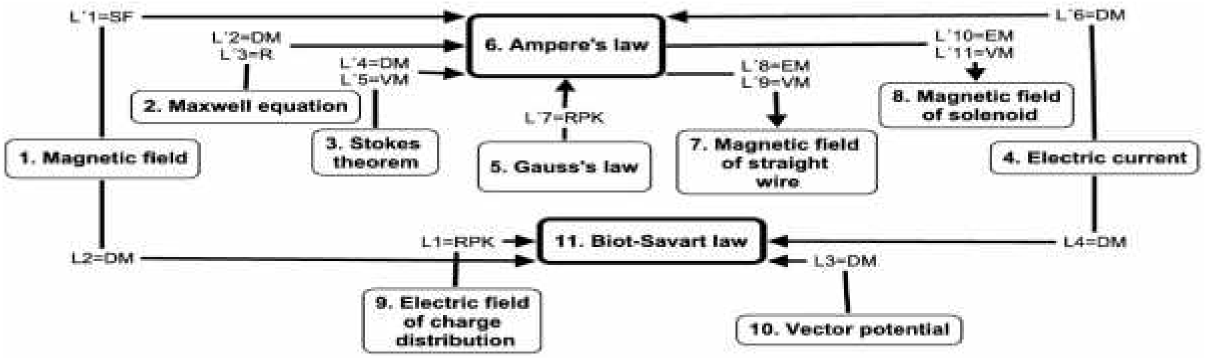

Fig 2. Concept map representing the knowledge organization of the textbook of FLS.

There are some incoming and outgoing links to Ampere's law (hierarchical structure) (e.g. Ampère's law connects to magnetic field via statement of fact, L´2=SF). There are only incoming links to Biot-Savart law (hierarchical structure), (e.g. electric field of charge distribution is utilized as an analogy (a type of RPK=L´1) to Biot-Savart law). Moreover, there are only two cross-links for the concept map of FLS. As Fig 2 shows, the knowledge organization of FLS has limited hierarchical levels, which means there are only few justifiable levels in the knowledge organization of FLS. The most dominant links in FLS are incoming links. Moreover, FLS includes few outgoing links and cross-links so its knowledge organization is not an interactive process. Ultimately, the knowledge organization of FLS can be interpreted as a simple structure that excludes interconnectedness but includes many disjointed concepts.

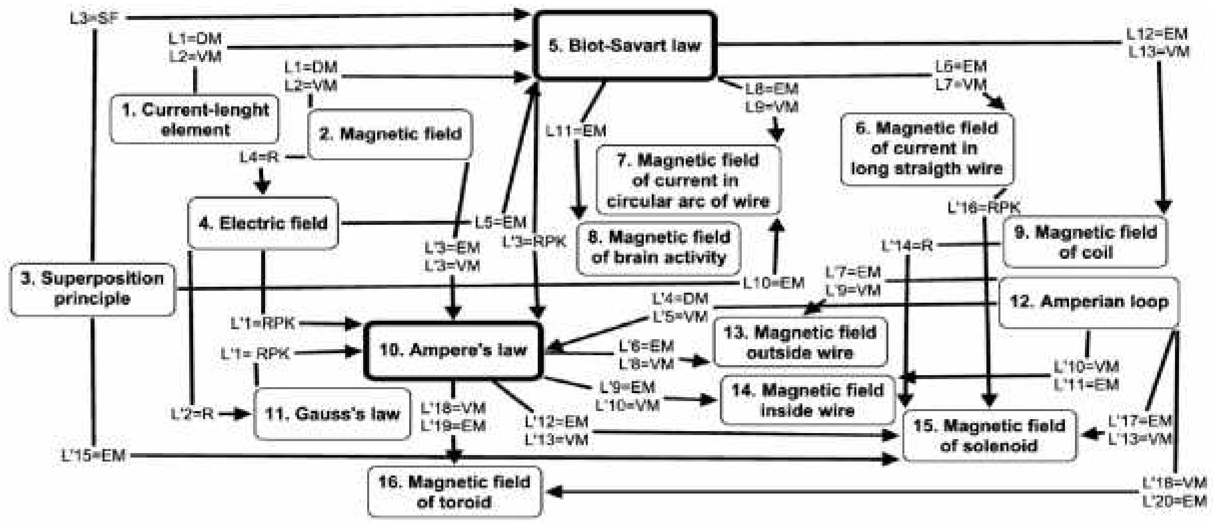

Fig 3. Concept map representing the knowledge organization of the textbook of HRW.

In contrast to FLS, Biot-Savart law is presented before Ampère's law in the textbook of HRW. There are only two dead end nodes in this concept map. There are incoming and outgoing links to Biot-Savart law as well as to Ampere's law. There are also some cross-links in this organization. As Fig 3 shows, knowledge organization of HRW includes many hierarchical levels. HRW describes high interactive process that includes some cross-links. Besides, the knowledge organization of HRW consists of many incoming and outgoing links. HRW includes only two disjointed concepts. Therefore, the knowledge organization of HRW is flexible and interconnected.

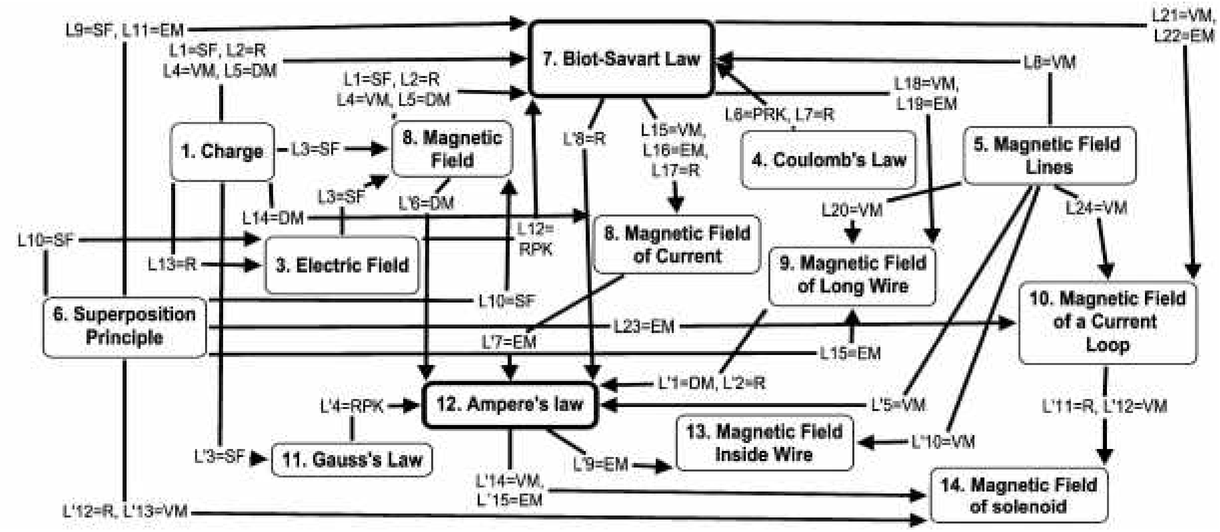

Fig 4. Concept map representing the knowledge organization of the textbook of Knight.

The organization of this concept map is somehow similar to HRW. In other words, there are some incoming and outgoing links to both core concepts. However, comparing HRW, there are more cross-links comparing to HRW. As Fig 4 shows, knowledge organization of Knight contains many hierarchical levels. Moreover, the knowledge organization of Knight is an interactive process that includes some cross-links. The knowledge organization of Knight includes many incoming as well as outgoing links. There is only one disjointed concept in the knowledge organization of Knight. Such an organization has flexible and interconnected structure. The knowledge organizations that are hierarchical and include interactive processes are more flexible and interconnected and therefore they are more beneficial for learning than simple structures.

CONCLUSION AND DISCUSSION

In this study, first the basic elements are specified. Second, a framework to categorize the links between the basic elements has been developed and validated by utilizing experts' ratings (resembles approach developed by Roseman et al., (2010)). Finally, the basic elements and links were presented by using concept maps and the knowledge organization of the textbooks was analyzed on the basis of the topological patterns in concept maps. On a basis of results introduced above, the research questions are answered as follows (the numbers refer to the research questions): 1) the links have different characteristics in the examined university physics textbooks. All textbooks used different types of modelling procedures to link the basic elements. However, the different textbooks used the links very differently. The FLS had only few links compared to other textbooks and the DM were the most utilized link type. In HRW, the link types of EM and VM were the most utilized ones. In Knight, there were substantially more links than in other textbooks and the different link types (especially VM, EM, and R) were utilized in versatile ways. 2) The knowledge organization of FLP has simple structure. As for knowledge organizations of HRW and Knight have flexible and interconnected structures. In conclusion, the knowledge organization of HRW and Knight are in many respects similar what comes to hierarchy and interactive process, and they are very different from the knowledge organization of FLS. Such fundamental differences in knowledge organization are bound to affect the views of the knowledge organization of physics that teachers and students obtain from the textbooks.

Here we have proposed a method to recognize basic elements and links between them within textbooks. We have shown that although basic elements for the same topics in different physics textbooks are similar, the textbooks apply different types, and number of links to connect basic elements and eventually their knowledge organization is different. These differences of knowledge organization are revealed by using concept maps, which show the structural patterns of knowledge organization of textbooks and make the comparison between textbooks possible.

Recognizing the knowledge organization in the textbooks is an important subject in education, which affects learning and teaching. This method might actively engage students to think about the basic elements, links, and finally knowledge organization of the textbooks, and thus promote students' understanding of different topics in textbooks. Moreover, using this method may help students to organize their own knowledge and thus encourage them to understand whether their knowledge is well organized or not. Furthermore, other studies verify the impact of textbooks on teachers learning, as discussed earlier (see Ball & Cohen, 1996; Davis & Krajcik, 2005). The proposed method of this study, which recognizes basic elements and categorizes links, could be applied to analyze the quality of texts. Previous studies discussed earlier (e.g. Roseman et al., 2010) have emphasized the specification of the key ideas and the connections among them within the textbooks, but few of them carried out such investigation. In this study, in addition to recognition of the basic elements in textbooks, we developed a specific framework to clarify the nature of the links that connect the key ideas, basic elements of knowledge organization.

This research is continuing to explore the knowledge organization of university teachers by using the same kind of analysis method that is discussed in this study. The comparison of the knowledge organization of university teachers and university textbooks can reveal interesting aspects having influence in science education and teaching.

Abstract: Learning does not take place only in the classroom. Nowadays, online teaching and learning has become a phenomenon and many believe that e-learning can be the next revolutionary change in education. E-learning is a way of learning supported by Information Communication Technologies (ICT) that makes it possible to deliver education and training to anyone, anytime and anywhere. Our research deals with the implementation of e-learning in the area of secondary education in Greece for teaching natural sciences. The Learning Management System (LMS) called Moodle (Modular Object Oriented Dynamic Learning Environment) was used for the creation of the virtual classroom. Asynchronous and synchronous communication was tried especially among the students, as well as between students and the instructor, aiming at cooperative learning. The main objectives of our study were to analyze the relationship of students' intention to use e-learning with selected constructs such as their attitude, perceived usefulness, perceived ease of use, self-efficacy of e-learning. The Technology Acceptance Model (TAM) is used in order to examine how students receive and how they use the Moodle platform. The positive attitude that is observed towards the model of blended learning and the Moodle platform did not appear to have high cross-correlation between use and intention of use. This fact was verified by the system's log files of students' participation in the attendance of internet courses and by the final acceptance questionnaire. The adoption of an appropriate pedagogical framework is needed in order to engage students and teachers in a LMS for teaching and learning natural sciences.

Keywords: E-learning, Sciences Education, Moodle, TAM, Secondary Education

BACKGROUND

Contemporary studies have focused largely on the examination of students' ideas/perceptions of concepts and phenomena within the field of natural sciences. In the following years, students have to develop a more active role in the educational process, and consequently the student must be the main person in the learning process. Contemporary instructional approaches expect students to be active producers of knowledge (Psycharis, 2011). Information and Communication Technologies (ICT) are considered to be largely applicable for natural sciences as they enable representation of phenomena, foster experimental study and enable the creation of models and problem solving applications (Duit, 1995, Psillos & Niedderer, 2002, Psycharis, 2011).

Offering distance education and using ICT for teaching natural sciences is neither a simple nor easy task. Quality guidelines for e-learning courses are needed (Kidney et al., 2007). Learning Management System (LMS) is a software platform for managing a coherent educational electronic system. In particular, through LMS the management of electronic classes and the educational material in general is made possible, such as developing classes through the platform authoring tools, introducing predesigned classes, and modifying, enriching or deleting their content. Monitor data are available to platform administrators and the teachers of the classes. The development of distance learning systems along with technological advancements enables the creation of a new dynamic technology in e-learning. Users' registration can thus be automated and access to classes can be controlled. Users' actions can be monitored from the moment they enter the platform to the moment the exit the system. This pedagogical methodology has to be near to the constructivist educational model (Martin-Blas & Serrano-Fernandez, 2009).

Moodle (Modular Object Oriented Dynamic Learning Environment) is an electronic learning environment (Learning Management System, LMS) which created in the 1990s by Martin Dugiamas, specializing in Computer Assisted Education (CAE). The development of Moodle was based on social constructivism emphasizing the importance of culture and context in understanding what occurs in society and constructing knowledge based on this understanding (Park, 2009). The present research was based on the use of Moodle 1.9.5 in teaching natural sciences in secondary education.

There are theoretical models that attempt to explain the relationship between user attitudes, perceptions, beliefs, and eventual system use. These include the Theory of Reasoned Action (TRA), the Theory of Planned Behavior (TPB), and the Technology Acceptance Model (TAM). Among these, TAM, proposed by Davis (1986) seems to be the most widely used by researchers. It is a model which explains the adoption behavior of computer systems by the users and calculates the level of acceptance. Figure 1 depicts TAM's three phases (Davis, 1986).

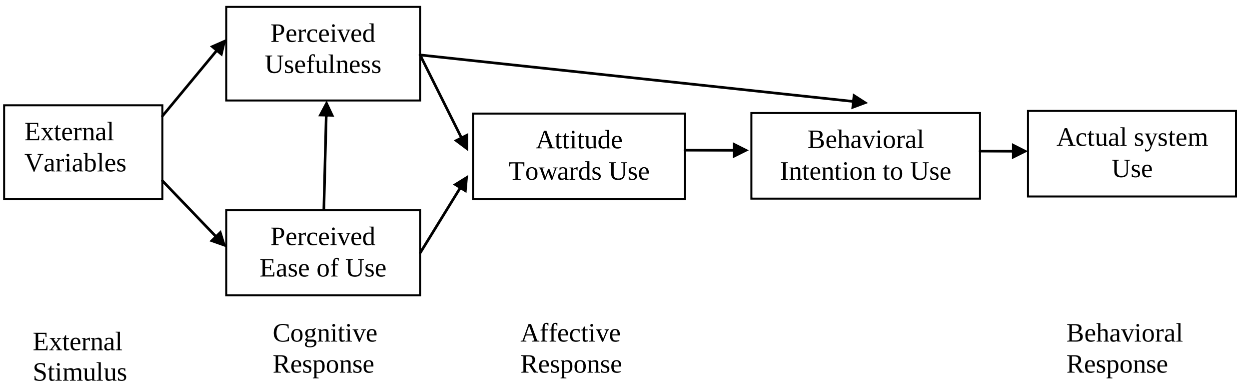

Figure 1: The three phases in TAM: Cognitive, Affective, Behavioral (Davis, 1986)

We used TAM for evaluating the Moodle platform in the framework of a course in natural sciences in secondary education in Greece. The TAM is an analytical simplification of how functionality and interface characteristics relate to adoption decisions. According to TAM, one's actual use of a technology system is influenced directly or indirectly by the user's behavioural intentions, attitude, perceived usefulness of the system, and perceived ease of the system (Davis, 1993). In TAM, technology acceptance and use is determined by behavioural intention (BI). BI in turn, is affected by Attitude Towards Use (ATT), as well as the direct and indirect effects of Perceived Ease of Use (PE) and Perceived Usefulness (PU). Both PE and PU jointly affect ATT, whilst PE has a direct impact on PU (Davis, 1986, Davis, 1993). TAM also proposes that external factors affect intention and actual use through mediated effects on perceived usefulness and perceived ease of use. Although TAM is considered as a well-recognized model in the field of information systems, little systematic research has been conducted in the LMS context for teaching natural sciences.

Selim (2003) argues that there is a need to investigate TAM with web-based learning. In his study, e-learning refers to pure, web-based, asynchronous learning. For Saadé, Nebebe and Tan (2007) university students' participation and involvement were important for successful e-learning systems. Therefore students' acceptance behavior should be assessed. They suggested that TAM is a solid theoretical model whose validity can extend to the e-learning context (Saadé et al., 2007).

FRAMEWORK AND PURPOSE

Aims of the research

One the main ambitions of our work was to get students acquainted with the model of blended learning as well as the use of Moodle environment. We implemented an on-line course as an extension of the face-to-face courses. We created, developed and applied an interactive learning environment for teaching natural sciences at secondary school level. Synchronous and a-synchronous communication was tried especially among the students as well as between students and the instructor aiming at cooperative learning. In the framework of the present research we explored the relation between perceived usability and actual ease of use of such a system, as well as the views towards a virtual learning environment in the model of blended learning.

Rationale

Students were faced up with time restrictions in school educational programs, the schools' infrastructure, the practical difficulties in computer and internet access and the established teacher-centered model. These limitations and the issues relating to the difficulty of applying an alternative pedagogical framework within the natural school space may be overcome by means of distance learning, through a particular LMS.

Our work examined the extent to which such an interactive platform can be used to eliminate such restrictions. We studied the levels of improvement in students' performance, their views towards the introduction of a LMS in natural sciences and also their levels of participation in interactive classes.

METHODS

This is a case study, and our sample consisted of 25 students (12 boys and 13 girls) of the Second Grade studying the course "General Physics", in a General Lyceum in Greece during the school year 2009-10. The learning level of the participants was characterized from good to excellent, based on the students' grades. One motivation for the students' participation was the awarding for participation in terms of grade, to a maximum percentage of 40% towards the final grade of the participants (60% from class performance and 40% from participation and performance in the LMS). The criterion for the school selection was the fact that it is a typical, district school. As far as the social status of the students is concerned, the majority of them came from agricultural or labour backgrounds (children of workmen or employers in private or public organizations), which corresponds to the vast majority of the economically active population in Greece.

In the first phase, the implementation and application of a scaled weekly plan of classes and activities was studied in the field of electric circuits. In this phase, the installation and organization of the Moodle platform was planned, the requirements with regard to hardware and software material were also determined and finally, the server for the webpage hosting the educational and learning environment, including a computer system for synchronous and asynchronous distance learning, was selected.

In the second phase, the efficiency of educators' intervention was applied and evaluated, based on results from spreadsheets. In addition, the use and response to the educational and learning environment was evaluated by means of the system's log files and the respective response questionnaire. The manner in which the study was conducted was based on the quantitative approach. The spreadsheets and questionnaire on meta-learning experience consisted of closed questions, in true-false and yes-no format.

The final response questionnaire consisted of closed questions, under the Likert evaluation format. The creation of the questionnaire was based on a study of relevance to the research questionnaires, bibliography and online websites. Additionally, Moodle environment is included in COLLES (Constructivist On-Line Learning Environment Survey) questionnaire, the examination of which has been helpful in forming some of the questions in this particular questionnaire. The system's log files include numerical data and picturing the participation (for example, entries to the system per student). The process of the data is based on descriptive, statistical methodology (data presentation in tables and figures). For performance examination in spreadsheets, on the first level, there is the normality test Kolmogorov-Smirnov and the t-test evaluation on dependent samples (performance before and after teaching). In addition, in the criterion Wilcoxon highlighted, rank was used to make the comparison (between performance before and after), in cases where there is a variation in the normality test.

RESULTS

The final questionnaire is examined in terms of validity and reliability. In order to establish the conceptual construct validity of the questionnaire, the factual structure was examined, using the principal components analysis method (Tables 1 & 2).

KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		,571

Table 1: Sample Efficiency

Reliability Statistics

Cronbach's Alpha	N of Items
,552	17

Table 2: Scale Reliability

The evaluation of reliability was based on the internal effect with criteria method, the Cronbach "a" method, the item-item correlation testing and the corrected item-total correlations, in order to evaluate each question under this scale. Data processing was performed using the SPSS program, version 17.

The participation demonstrated that during the experimental application examined by investigation the log files were decreasing. The students' outside school preoccupations (such as educational activities, sports, etc.) result in diminishing free time, which acted as a preventive factor to consistent participation. Students claimed they prefer to surf the internet without particular purpose, including social networking webpages such as facebook, rather than get involved in, or spend extra time on, the subject of physics on the internet. The performance grade (a percentage of 40% of total grade) as a means of motivation and award for participation did not appear to play a significant part. This is clearly due to the recently noted indifference of the students towards subjects of general education and their concentration on routine subjects. The examination system in Greece for entering Higher Education has, therefore, formed particular tendencies and results in similar views and behaviours on the part of the students, as far as ICT are concerned.

Factual correlations (Table 3) in the questionnaire, as answered by the students, show that the Perceived Usefulness (PU) of the System is loosely related to the positive view towards Environment Attitudes (EA) and Collaboration and Teaching Attitudes (CTA), whereas it is not related at all to the behavior towards use or Actual System Use (AS). In addition, Perceived Ease of Use (PE) is not related to positive views towards the system (EA) and its relation to Intention of Use (AS) is limited. Finally, there has been found no relation between positive views towards the system (EA) and Intention of Use (AS). The conclusions as set above have been taken into consideration and have been confirmed in the system's log files (course view) (Figure 2).

Component Correlation Matrix

Component	1 (PU)	2 (AS)	3 (CTA)	4 (PE)	5 (EA)
1 (PU)	1,000				
2 (AS)	-,062	1,000			
3 (CTA)	**-,269**	-,082	1,000		
4 (PE)	**,217**	**-,240**	-,189	1,000	
5 (EA)	**,328**	-,024	-,125	,005	1,000

Table 3: Matrix of factual correlations p<0,01

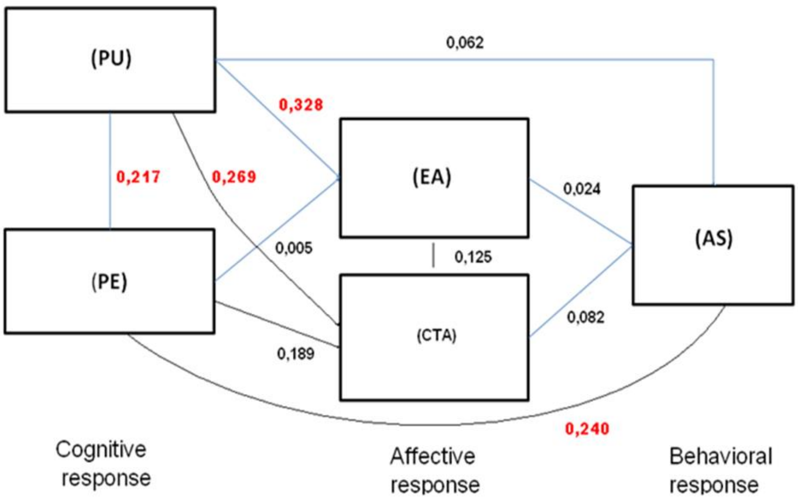

Figure 2: Factual correlation of response questionnaire

The students, in the majority being acquainted with PC use and the internet, can generally learn and use easily an interactive environment, such as Moodle. The collaboration among the students working in groups has had an effect on a third of the students' sample, who changed their decisions towards the correct answer as shown in the study of the answers to the questionnaires on metacognition experience.

CONCLUSIONS AND IMPLICATIONS

In general, students' concentration tends to be positively correlated to their intention to use Moodle for natural sciences. Thus, we should recognize these users as not only system users but also learners. Students can also perceive its usability in terms of the opportunities it can offer. However, the relation between; positive attitudes towards the system, its use and intention of use with perception of its usability, and ease of use is affected on a large scale by other factors. The need for free time, the general views towards school reality and learning in school, the way of life (role-models, values, behaviours) depicted in mass media, the mentality and practices of most educators (with limited exceptions), the lack of team-working experience, are all such conditions which require examination in order to establish how much they relate to the success or failure of e-learning.

The mode of teaching natural sciences and other subjects in schools is not oriented towards team-building learning activities and as a result the students' levels of collaboration are low, since they had never before participated in such an experience. As far as the development, application and function of an interactive environment is concerned, the educator who should attempt such a task shall be faced with difficulties technical and functional in nature from the start. They should be quite certain what is to be used, how to use it, where to publish it, who has the right or the obligation to access it and who controls it. As a consequence, issues such as hosting and platform installation to a larger or smaller extent, can be considered as an "adventurous" and demanding attempt. The knowledge required has not yet been available to Greek educators today by means of any educational programme (Kalogiannakis, 2010).

It should be possible for the use of interactive educational platforms to achieve the aims set, if the students are motivated towards the educational procedure and take full advantage of the possibilities that technology offers to direct and indirect effects within the educational environment. We shall not always consider anything new as something innovative and something to be adopted without control and consideration of other factors.

The choice of an appropriate pedagogical framework, the development, structuring and planning of learning through LMS require that educators who undertake such a project are familiar with ICT, well trained in pedagogical issues as well as in ICT, in order to support the achievement of teaching aims.

The findings of this research are valuable for the assessment of e-learning services in secondary education for teaching natural sciences which will pave the way for future improvement. Our findings should be interpreted within the limitations of a small-scale exploration study and more systematic research is needed. This type of research needs to be implemented in other e-learning circumstances or infrastructures. Future studies should also investigate the role of adding other variables such user experiences and user characteristics to those originally employed in the model. Apart from careful planning and determination of aims, it is vital that certain factors should be taken into account, including educational staff, material and procedures.

A GAME IN THE CLASSROOM: WHAT DO STUDENTS LEARN?

Eric Sanchez
eric.sanchez@ens-lyon.fr
EducTice/S2HEP EA 4148, Ecole Normale Supérieure de Lyon

Abstract: This paper describes an empirical study relating to the use of a serious game in learning how to establish the chronology of geological events. This research involved 61 16-17 year-old students. The students' challenge consisted in reproducing different images of geological cuts with *Chronocoupe*, a game that simulates the consequences of geological events. The research is based on the *Theory of Didactical Situations* (Brousseau, 1986) and recent research in the field of the use of *serious games* for educational purposes (Egenfeldt-Nielsen, 2010). It aims at addressing the following questions: (a) Which elements should be taken into account in designing the game in order to induce the learner/gamer to engage in epistemic activities? (b) What do students learn when they succeed in the game?

The digital records of students' usage of the game allows one to draw behavioral and epistemic models of students (Wenger, 1987). Data sources of the study include the results of a test to assess students' capacity to determine the chronology of geological events as well.

The study shows that the design of the software must take into account that the students primarily use a trial and error strategy and that they are reluctant to shift to a strategy based on the analysis of the images to be reproduced. The study also shows that the students learn procedural knowledge, but they are not aware of the principles that they use when they are asked to establish the chronology of geological events.

Keywords: serious game, geology, science learning, epistemic modeling

1) BACKGROUND, FRAMEWORK AND PURPOSE

As gaming is one of the of the most popular occupations of youths, an increasing number of science teachers integrate serious games – *e.g.* digital games designed for educational purposes - into their teaching practices. However, few empirical studies have been carried out to explore the value of serious games for science education. It can certainly be said that digital games facilitate learning, but the evidence for saying any more than this is weak as most studies focus on the impact of game-based learning on students' motivation (Egenfeldt-Nielsen, 2010).

Our research aims at producing empirical evidence for the effectiveness of game-based learning for science education. Our work is grounded on the Piagetian hypothesis that states that learning is adaptive. Learning is considered to be an adaptive process (Piaget & Inhelder, 1966), the learner/player incorporates the game experience into an already existing framework (*assimilation*), while reframing his/her mental representations to fit new experiences (*accommodation*). Our work is also based on the *Theory of Didactical Situations* (TDS) (Balacheff, Cooper, & Sutherland, 1997). According to Brousseau, there is a strong link between problem solving (in a learning situation), and knowledge (as an instrument to mastering the situation). The learning process results from interactions between the learner and a *didactical milieu* (*Ibid*.). The *didactical milieu* encompasses all the elements of the situation with which the learner deals during his/her activity. These elements are concrete, symbolic or human.

In our research, the TDS is employed to design the game (as a *didactical milieu*) and the setting of the learning session. The session is an *a-didactical situation* (*Ibid*.). This means that the objectives of the teacher are hidden, while the activity appears driven by exploration. As a result, the learner doesn't need to interpret the expectations of the teacher to succeed in the game (Ahuja, Mitra, Kumar, & Singh, 1995). The theory is also used to analyze the outcomes of the study by focusing on interactions between the learner/gamer and the game.

In this paper we address the following questions:

- Which elements should be taken into account for game design in order to permit the learner/gamer to be engaged in epistemic activities?
- What do students learn when they succeed in the game?

2) METHODS AND SAMPLES

Chronocoupe is a *serious game* designed for geology teaching. It is possible to download the software for free on the website of the author. The interface of the game (fig. 1) shows an image of a geological cut that can be generated by clicking the *event-buttons* (seven different geological events are implemented). Clicking an *event-button* modifies the image. For example, clicking the sedimentary button adds sedimentary layers and clicking the *fold-button* folds all the previous geological features. The game consists in reproducing the images of five geological cuts. The learner/gamer can compare his/her images with the images to be reproduced at any moment by clicking on the image. He/she is allowed to cancel only the last click, but a *restart button* allows him/her to restart the game. It is thus very difficult to reproduce an image by using a trial and error strategy.

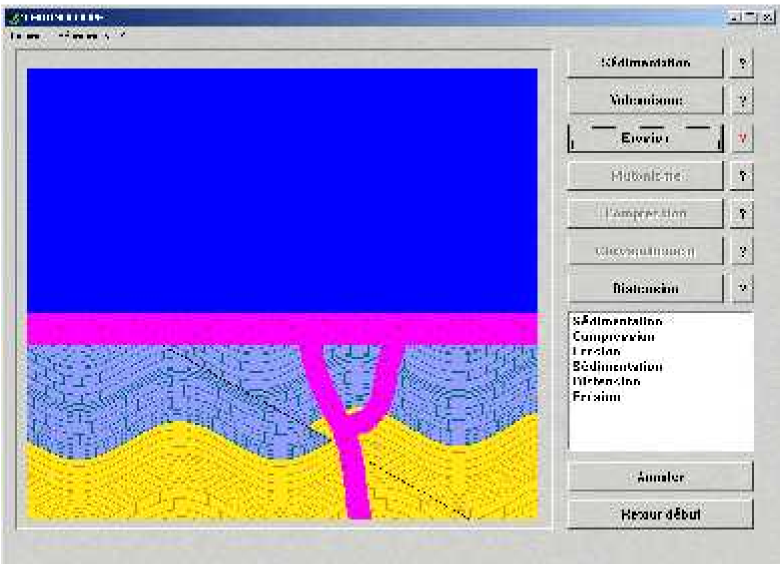

Fig. 1: *Chronocoupe*

The learner/gamer's success depends on his/her capacity to determine the geological event chronology of the different images displayed by the game. The chronology can be determined by applying the principles of stratigraphy. The *principle of superposition* states that, given normal conditions of deposition, new sediment layers deposit on the top of previous sediment layers. The *cross-cutting relationships principle* states that the geologic feature which cuts another is the younger of the two features. *Chronocoupe* is both a serious game and a simulation that simulates the forming of geological features and allows the player to explore the consequences of the simulation.

The experimentation was held with a sample composed of 61 students in the second year of upper secondary school in France (ISCED level 3A-16/17 years old). Each student used the computer individually. The students were asked to reproduce five images of geological cuts. The images were similar in terms of difficulty to reproduce. Different geological concepts, such as sedimentary process, magmatism and tectonics, were taught during previous teaching sessions.

The methodology of the research is based on the recording of the students' clicks (log files) to model each individual student's behavior. The log files are used to draw a chronogram for each student. This was done with a Microsoft Excel file designed by the author. A chronogram is a time line with colored bars that indicate the different clicks during the experimentation (fig. 2). Three indicators are used to compose a behavioral and epistemological model (Wenger, 1987) of the learner/gamer:

(a) The time devoted to reproduce an image indicates students' capacity to determine the chronology of geological events and to apply the principles of stratigraphy;

(b) The time devoted to the observation of the image to be reproduced is an indicator of the students' strategies. A short time indicates that the student doesn't base his/her chronology on a precise observation of the image, adopting a trial and error strategy instead.

(c) A high number of clicks of the restart button also indicates a trial and error strategy.

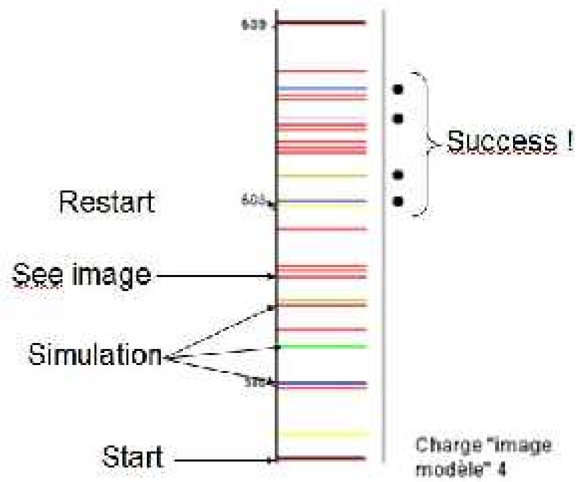

Fig. 2: Extract of a chronogram

At the end of the activity, the students were asked to take a test that consisted in determining the geological event chronology of an outcrop's image and to answer a short questionnaire. Due to difficulties during data gathering, only half of the students answered the questionnaire, but the log files of 42 students were recorded and analyzed.

3) RESULTS

a. Students' capacity to reproduce the images

The average time devoted to reproduce the images (fig. 3) decreases over the course of the experimentation from a maximum of 4 minutes 12 seconds for the second image to 1 minute 36 seconds. Furthermore, inter-personal variability decreases. This result can be interpreted as the development of the capacity of the students to reproduce the *images* and the homogenization of this capacity for the whole sample of our study.

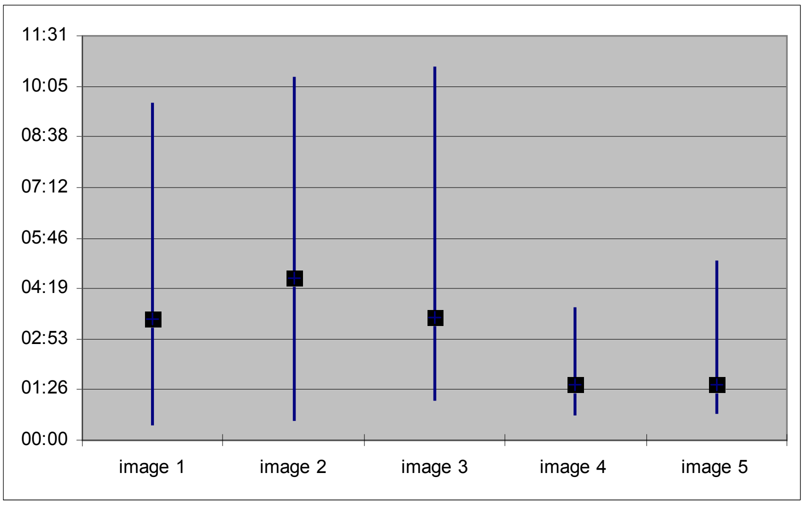

Fig. 3: Average time for the different images

b. Students' strategy shift

Regarding the strategies adopted by students, the comparison of two case studies, the students Elodie and Marie, illustrates two types of behavior. Marie completed the challenge in more than 17 minutes. She failed at reproducing two images. The chronogram shows that she observed the images to be reproduced very often, but during a very short time, usually by a 2 or 3 second glimpse, with 6 seconds as a maximum during the whole session. She very frequently used the *restart button*. All these observations constitute evidence that Marie's strategy consisted of a trial and error strategy, mostly based on chance. This was confirmed by her answers to the questionnaire. The short time devoted to the observation of the image to reproduce indicates that she was not engaged in a precise identification of the clues in the picture that can be used to determine the chronology. In Elodie's case, the session ended in approximately 11 minutes and she succeeded in reproducing all the images. During the first part of the session, Elodie's chronogram is similar to Marie's chronogram: frequent clicks on the *restart button* and short glimpses of the images to be reproduced. In the second part of the session, Elodie changed her strategy. The time devoted to the image observation was longer, 16 seconds as a maximum (for the last image) and the use of the *restart button* was rare (none for the last image). Her strategy seems to be based on a precise analysis of the image. The evolution of the average number of clicks on the *restart button* for the whole group shows that this use decreased during the session. This shows that a majority of students shifted a trial and error strategy to a strategy based on the use of the principles of stratigraphy. The students' answers to the questionnaire confirm this conclusion.

c. Transfer of knowledge

At the end of the session, 20 students from the 24 who passed the final test were able to identify the chronology of geological events on an outcrop's photograph, but only one of them was able to justify his/her response and 4 gave an incomplete explanation. Playing with the game led the students to learn how to identify the chronology of geological events, but they were not able to articulate the knowledge that they used. When they answered the questionnaire, several students themselves expressed that they were reluctant to consider that they had learned something by playing: "*It was fun, but, without the help of a teacher, one cannot really learn something*". The fact that students are often reluctant to consider that they can learn by gaming has been observed in different studies (Egenfeldt-Nielsen, 2007).

4) CONCLUSIONS AND IMPLICATIONS

The design of the gameplay has a significant impact on the learning process. The strategy used by the students is, at a preliminary step, a trial and error strategy based on chance. The students shift to a strategy that involves the knowledge that has to be learnt, if the design of the software disqualifies this trial and error strategy. Starting from this point, a game, as a *didactical milieu*, can be used by the students to assess their decisions and chosen strategy and, therefore, can help them to be autonomous (Sanchez, 2011). Indeed, being autonomous means that the learner/player gets the opportunity to assess his/her strategy by her/himself and then decide if a given decision or action is relevant or not. Assessing implies getting feedback and it is clear that feedback is a crucial element in a game. Therefore, game-based learning results from interactions and we can state that it is worthwhile to adopt a point of view that considers games as situations rather than artifacts (Sanchez & Jouneau-Sion, 2010). Thus serious games are *spaces of reflexivity*, where the learner/player can assess his/her way of thinking and acting. Starting from this point, the term *serious play* is more relevant than the term *serious game* to describe this type of educational practice.

By gaming, the students can develop scientific knowledge. This knowledge is embedded into the game. The students can play with this scientific model, explore the different consequences of their choices and identify properties of the model. The relevance of the scientific model embedded in a game is an important issue to teachers.

The results also indicate that the challenge faced by the students when playing must be inside their zone of proximal development (Malone & Lepper, 1987; Vygotski, 1934). Not all the students managed to succeed in reproducing the images. The design of the game must take into account the necessity to develop students' self confidence in their capability to achieve the challenge.

Our conclusion is that serious games can be implemented in the classroom to teach scientific concepts. Nevertheless, one should expect the learning to consist mostly of procedural knowledge. Indeed, there is a difference between "trying to master the rules of the game and recognizing the ways those rules structure our perception of reality" (Jenkins, Clinton, Purushotma, Robison, & Weigel, 2006). The students do not develop declarative knowledge without reflection and debriefing (Garris, Ahlers, & Driskell, 2002). Some students failed at reproducing the images because the challenge was too difficult. This result emphasizes the importance of the teacher for helping the students to be aware of the implicit knowledge that they use in a specific situation in order to solve a specific problem. This step, called *institutionalization* by Brousseau (Balacheff, Cooper, & Sutherland, 1997; Brousseau, 1998) and underlined by Habgood (Habgood, 2007), consists in pointing out that the contextualized and personal knowledge used for gaming is universal and scientific.

INFLUENCE OF CONNECTIVISM ON SCIENCE EDUCATION WITH EMPHASIS ON EXPERIMENTS

Eva Trnova[1] *and Josef Trna*[1]
[1]Masaryk University, Brno, Czech Republic, EU

Abstract: The paper presents research results of connectivistic influence on science education with emphasis on experiments. Fast ICT development influences science teaching and learning without us realising this. Implementation of science experiments is also strongly influenced by ICT. Thus a need occurred to examine these connectivistic influences on science education. This study describes a research which focussed on the following issues: identification of connectivistic factors and determination of the extending of their influence on science education; creation of connectivistic educational tools and techniques in science education; implementation of connectivistic education tools and techniques into science teaching and learning and science teachers training. School experiments namely the changes in their form and role in science education came under scrutiny. With the aid of the created research method, the collaborative action research based on ICT efficiency of connectivistic tools and methods in science education was researched and confirmed.

Keywords: action research; connectivism; ICT; science education; science experiments.

1 BACKGROUND, FRAMEWORK, AND PURPOSE

Science education is affected by the fast development of information and communication technologies (hereinafter ICT). The use of computers in the operating of school experiments and processing of observed results has been taken for granted. The Internet is becoming an ever more significant source of information including gaining data from distant laboratories. Records of experiment may be easily taken by digital and video cameras and further computer processed. Special computer software allow for animation, modelling and simulation of experiments. The use of the Internet as a communication network gives the students a whole number of options for information sharing, discussions, common problem solving, etc. We may anticipate creation of other significant ICT applications (holographic projection etc.).

ICT is being used by teachers as well as by students. ICT significantly becomes involved in teaching through the use of projectors, interactive boards, computer processed technology teaching elements including experiments etc. But there are differences between teachers´ and students´ attitudes towards ICT. D. Oblinger and J. Oblinger (2005) describe today's students as the Net Generation (Net Gen), who have grown up with widespread access to ICT and have spent their entire lives surrounded by and using computers, videogames, digital music players, video-cams, cell phones, and all the other toys and tools of the digital age. According to the above-mentioned authors, the Net Generation has some features which are different from previous generations and which affect their education. Here are the ones that influence instruction most:

- The Net Generation often intuitively uses a variety of ICT without an instruction manual so their understanding of the technology may be shallow.
- The Net Generation is more visually literate than previous generations, but because of the availability of visual media, their text literacy may be less well developed than the literacy of previous cohorts. Most students (73 %) prefer to use the Internet to libraries for research and they know how to find valid information on the Web (Online Computer Library Center, 2002). However, they realize that the Web does not meet all their information needs.

- In connection with playing a game or responding the Net Generation sometimes prefers speed to accuracy. They do multitask, move quickly from one activity to another and sometimes perform them simultaneously.
- Most Net Generation learners prefer to learn by doing rather than by being told what to do. Net Gen students learn well through inquiry - by exploring for themselves or with their peers. This exploratory style enables them to retain information better and to use it in creative, meaningful ways (Tapscott, 1998).
- The Net Generation often prefers to learn and work in teams. A peer-to-peer approach, where students help each other, is common as well. In fact, Net Generation learners consider peers more credible than teachers in terms of determining what is worth paying attention to (Manuel, 2002).

Other authors also state that children growing up with modern information technology are fundamentally different from previous generations of learners and express it using special naming such as the Nintendo Generation, Millennials, Digital Natives or Generation Z.

The fact that today's students are named by various above mentioned names brings along unique learning style preferences and worldviews. The above mentioned findings have led to the origin of a new educational theory – connectivism as "a learning theory for a digital age". Its founder, G. Siemens (2005) recommends extending the currently existing educational theories of behaviourism, cognitivism and constructivism. Constructivism as the currently accepted educational theory suggests that students create knowledge as they attempt to understand their experiences. Siemens states that learning is a network phenomenon, influenced (aided) by socialization and technology.

We continue to consider the principles of constructivism in science education fully valid and efficient which is confirmed by researches (Trna, Trnova & Vaculova, 2010) etc. Crucial impulses brought about by connectivism have to be accepted and examined: "Learning is no longer an internal, individualistic activity. Education has been slow to recognize the impact of new learning tools and the environmental changes. The ability to learn what we need for tomorrow is more important than what we know today. When knowledge, however, is needed, but not known, the ability to plug into sources to meet the requirements becomes a vital skill. As knowledge continues to grow and evolve, access to what is needed is more important than what the learner currently possesses" (Siemens, 2004). Returning back to the features of today's learners it is possible to recognize the reflection in the first principles of connectivism which were established by G. Siemens:

- Learning and knowledge rests in diversity of opinions.
- Learning is a process of connecting specialized nodes or information sources.
- Learning may reside in non-human appliances.
- Capacity to know more is more critical than what is currently known.
- Nurturing and maintaining connections is needed to facilitate continual learning.
- Ability to see connections between fields, ideas, and concepts is a core skill.
- Currency (accurate, up-to-date knowledge) is the intent of all connectivistic learning activities.
- Decision-making is "itself" a learning process. Choosing what to learn and the meaning of incoming information is seen through the lens of a shifting reality. While there is a right answer now, it may be wrong tomorrow due to alterations in the information climate affecting the decision (Siemens, 2005, p. 5).

Science education is also influenced by connectivism and it would be suitable to examine possible connectivistic influences on science and technology education. Our research is concerned with this problem and is focused on the impact of experiments.

2 RATIONALES

Today science education plays an important role in educational systems and in many systems it has the goal of enhancing scientific literacy in students (American Association for the Advancement of Science, 1989), but the interest of students in science has been significantly decreasing. This negative situation has many causes and factors but based on the above mentioned text the way science is taught in schools and different learning style of today's learners are the main ones. In this context it is necessary to consider how to change teaching methods and increase students´ motivation for science. This study is a start towards alleviating these factors, and also increases the familiarity of ICT use for collaborative work among teachers and trainers across the world. Our core idea is to use ICT for the dissemination and upgrading of ideas, curricular materials and effective teaching methods amongst teachers. Connectivistic ideas of sharing knowledge can be applied even to teachers.

To increase the interest of students in science it is necessary to respect the stated generation differences and understand what they prefer, what they are interested in, how they learn. Like all students, they learn more effectively when taught in accordance with their learning style preferences and when their worldviews are acknowledged. So it is necessary to change teaching methods and materials to accommodate the Generation learners better and to correlate them with improvements in students' attitudes and performances. Therefore the need arose to examine possible connectivistic influences on science education. Our research is focused on the following issues:

(i) Identification of connectivistic factors and determination of extend of their influence on science education.

(ii) Creation of connectivistic educational tools and techniques in science education.

(iii) Implementation of connectivistic educational tools and techniques into science teaching/learning and science teachers training.

To narrow the investigated issue we focussed on the implementation of experiments.

3 METHODS

Teachers need research-based innovative educational methods for the upgrading of their teaching. The motivation of students and teachers in science education is the core of up to date teaching/learning. A very urgent task for educational research is to find appropriate educational methods and tools which have to be implemented into teachers' training and then in teaching/learning science. To monitor the set out connectivistic factors, we used a method of a design-based research. It is a development research. This research differs from other types of researches. Unlike the empirical research, hypothesis and research questions are not determined, but the problem is defined to be solved. Design-based research is a new trend in educational research. The used methodology can be described as a cycle: analysis of a practical problem, development of solutions, iterative testing of solutions, reflection and implementation. This methodology was implemented into our research. The scheme compiled by T. C. Reeves (2006) (see Figure 1) presents a comparison between the design-based (development) research and empirical research.

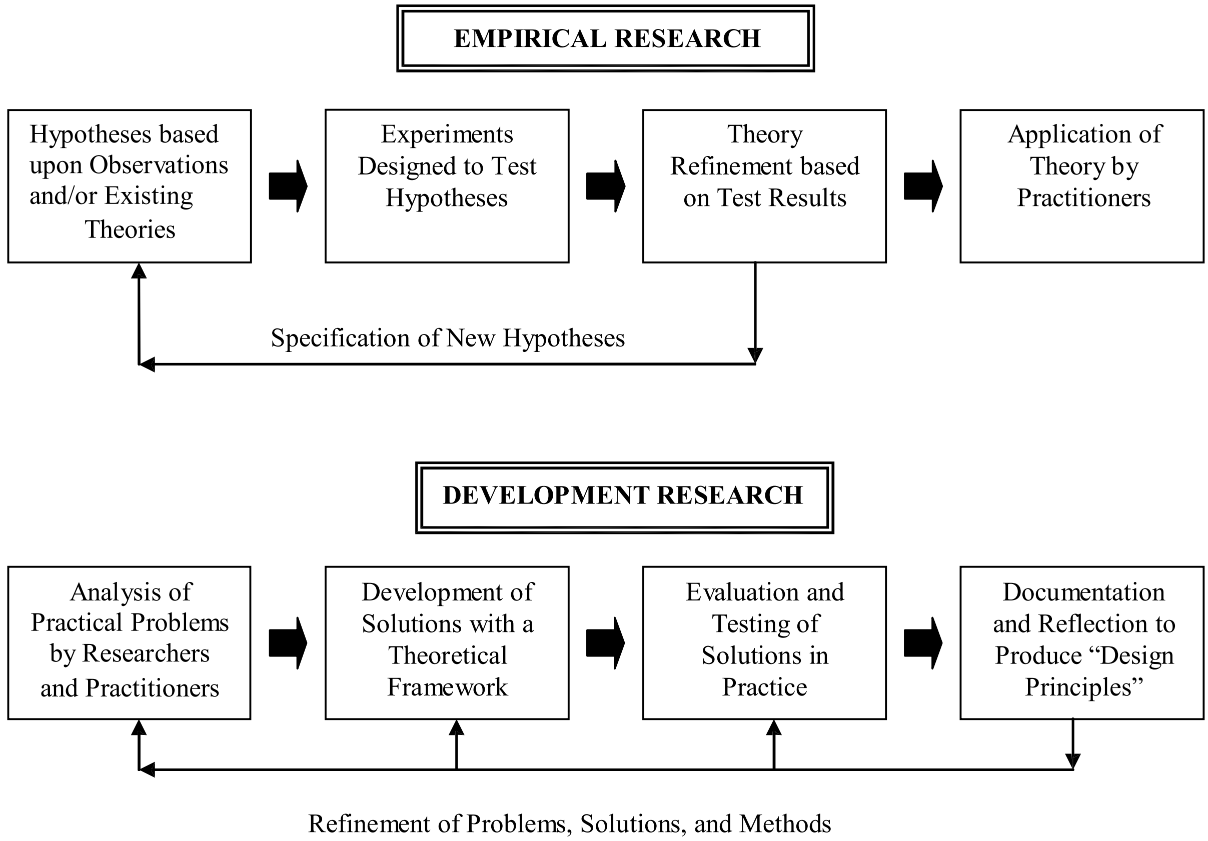

Figure 1. Empirical and development approaches to IT research (Reeves, 2006)

The core of design-based research is to focus on the creation of a new product. This research offers solutions to problems that have only been solved partially so far and relevant instruments and methods (Järvinen, 2004). The main advantage of the design-based research is its close connection with educational practice. Many results of other researchers are considered as separate from practice and are not understood by teachers. The basic principle and advantage of the design-based research is the close cooperation between researchers and teachers, which is a prerequisite of direct use of the research outputs in everyday practice.

The above-mentioned reasons led us to use design-based research to address the issue of the implementation of connectivism into science and technology education. These methods were created within the frame of collaborative action research based on ICT which can be used as a vehicle for international cooperation with effective exploitation of ICT. Sufficient methods/tools for the research objectives were:
(i) Factor analysis
(ii) Didactic analysis and development of connectivistic teaching techniques and tools
(iii) Collaborative action research based on ICT (Trna & Trnova, 2010) for verification of efficiency of developed connectivistic teaching/learning techniques and tools
Data generating methods were available such as through the use of questionnaires, observations, interviews, tests, students' and teachers' portfolios. Collaborative action research based on ICT was carried out in the following form: it was carried out on-line in two classes, one class in the Czech Republic and the second one in Portugal; it was prepared and managed by two cooperating teachers in the Czech Republic and in Portugal; teaching was carried on at the same time with the use of on-line communication (Skype etc.).

4 RESULTS

(i) + (ii) We have discovered several connectivistic factors that show today in the teaching of science and application of experiments: These include namely:

- Computer control of experiments and computer processing of measured data
- Getting of manuals for experiments from the Internet
- Digital recording and web presentations of experiments
- Knowledge sharing and distribution across a network
- Creation of learning structures using networks etc.

We have developed the set of connectivistic teaching/learning techniques and tools applicable primarily in implementation in ICT based collaborative action research:

(a) Application of a single communication language (English): All students have to be acquainted with English terminology also in science teaching (English descriptions of experiments etc.).

(b) Application of ICT communication technologies: Both students and teachers have to command ICT, namely their on-line variants. A web portal with curricular materials has been created which was accessible to students and teachers. The portal contained descriptions of experiments, worksheets, advice to students, etc.

(c) The use of cooperating students' knowledge: both cooperating classes of students made their own experiments the results of which they mutually communicated with belief that they were carried out correctly. Thus, knowledge of others was utilised in a network. In accordance with the ideas of connectivism acquired knowledge can be considered as connective knowledge. Connective knowledge requires an interaction. More to the point, connective knowledge is knowledge of the connection (Downes, 2005).

(d) Creation of communication connections: Students of one class carried out experiments under the on-line instructions of the cooperating partners. Thus the students were creating the skill how to gain the necessary knowledge and skills.

(iii) We used collaborative action research based on ICT. The "action" factor was collaboration among teachers and students from Portugal and the Czech Republic to upgrade teaching and learning using ICT and the innovative school experimentation. Students were involved in the process of learning and were also encouraged to play a teaching role with respect to their peers. The topic chosen was "photosynthesis" by the use of criteria: position of the topic in the curriculum of the countries, importance of the topic for students' cognitive development, and the level of interest for students. The factors considered for the selection of students were age and ability. It was decided that the students should be approximately the same age, promoting an interest to collaborate students. That is why were selected students of intact classes from secondary schools and 15-16 years of age. They needed to be able to communicate in the English language and had skill in the use of ICT (email, ICQ, Skype, and video-conferencing). For this study, teachers prepared a schedule of their own and their students´ activities for each of the collaborative lessons. The teachers collaboratively developed worksheets, power-point presentations, videos, experiments, learning tasks, etc. Reflection was a very important part of this research.

Pre-test and post-test: Pre-test data was gathered about what students already know about the learning focus in order to ascertain those changes in students´ knowledge and skills. Below is one example of pre-test and post-test that focused on one aspect of this work (see Table 1).

Questionnaire: Students completed such a questionnaire that focused on their reflections on this innovative bilateral collaboration and ICT use. Their answers indicate very high levels of both motivation and engagement with the educational process; they learnt a great deal (see Table 2).

Students´ view of teachers´ work in on-line environment and their ability to manage unusual instruction is also very interesting (see Table 3):

Table 1. Pre-test and post-test findings

Pre-test findings:		
Statement	***Correct answers (%) Czech students***	***Correct answers (%) Portuguese students***
In winter, most plants live of the reserves they accumulated during the summer.	56,2	44,4
Post-test findings:		
The plant stores glucose for later use in seeds, roots and fruits.	87,4	81,5

Table 2. Responses by Portuguese/Czech students

In the statements listed below are some of the aspects related to the activities shared with your Czech colleagues. Choose the option which best expresses your opinion.					
N=27/21	*Disagree*	*Partially Agree*	*Agree*	*Strongly Agree*	*No opinion*
The partnership helped you to better understand certain aspects of this topic.	*7%* *0%*	*33%* *29%*	*42%* *47%*	*14%* *19%*	*4%* *5%*
You would have achieved the objectives of this topic better by interacting only with your classroom classmates.	*33%* *29%*	*52%* *29%*	*4%* *29%*	*4%* *0%*	*7%* *13%*

Table 3. Responses by Portuguese/Czech students

Your teacher's performance (on the aspects listed below) contributed to learning the topic in an online environment. Choose the option that best expresses your opinion.					
N=27/21	*Disagree*	*Partially Agree*	*Agree*	*Strongly Agree*	*No opinion*
The teacher showed enthusiasm in sharing experiences between students from both countries.	0% 0%	4% 14%	33% 33%	63% 48%	0% 5%
The teacher demonstrated a capacity to motivate students in this topic.	0% 0%	7% 19%	63% 43%	30% 33%	0% 5%
The teacher demonstrated dynamism to conduct the present activities.	0% 0%	7% 38%	41% 33%	52% 24%	0% 5%
The teacher's interaction and monitoring of students´ on-line work was effective.	0% 0%	11% 14%	33% 48%	56% 33%	0% 5%
The teacher encouraged interaction both within and between groups.	0% 0%	11% 19%	41% 43%	48% 24%	0% 14%

5 CONCLUSIONS

The main outcomes of the research and implementation of connectivistic techniques and tools into science school experimentation:

- Strong motivation of students and teachers by communication with colleagues in other country, new information, applications of new knowledge, new personal contacts etc.
- Exchange of experience between teachers (experiments etc.).
- Teachers' and students' improvement of skills to use ICT and English language.

- Gaining of collaboration competencies between teachers and among students.
- Team collaboration among students and teachers.
- More effective acquisition of science knowledge and skills.

The form and role of experiment in science education has been changing which has to be further examined. With the help of design-based research, suitable teaching tools and techniques have to be created for teachers to implement the experiment in teaching in the most efficient way (Hodson, 1988). We may anticipate a growing importance of simple experiments the students and teachers will creatively work with using ICT. Our research results indicate that students learned with interest, and their knowledge and skills were better than would be expected using standard methods free of connectivism. On this basis, these connectivistic tools and techniques produced very positive outcomes for students and teachers-action researchers.

THE STATES-OF-MATTER APPROACH (SOMA) TO HIGH-SCHOOL CHEMISTRY: TEXTBOOK AND EVALUATION BY TEACHERS

Georgios Tsaparlis[1] *and Evangelos Pyrgas*[1]

[1]University of Ioannina, Department of Chemistry, GR-451 10 Ioannina, Greece

Abstract: Chemistry, as a high-school subject for all, should aim to supply students with scientific and chemical literacy (including chemical culture), to cultivate higher-order cognitive skills, and to be a useful, interesting, and enjoyable subject. A chemistry programme for all students in grades ten and eleven (ages 15-17) that was proposed in Greece some years ago, introduces chemistry through the separate study of the three states of matter [the *states-of-matter approach* (*SOMA*)]. There are three major units in the programme, namely: (A) Air, Gases, and the Gaseous State, (B) Salt, Salts, and the Solid State; (C) Water, Liquids, and the Liquid State. Following the proposal, a textbook was written that adopted SOMA. The book was evaluated by four experienced upper secondary chemistry teachers, (and one university chemistry professor)**.** The evaluation examined the following dimensions of scientific and chemical literacy: cognitive domain (learning), affective domain (satisfaction), relevance to students' life (chemistry and life), and higher-order cognitive skills (HOCS). The teachers found the book complete, dealing with many matters, and its level was advanced (difficult in some cases). SOMA was judged very original, having a logical flow of the material, and in general the evaluators liked it. In addition, the book fulfills, in general, the aims of chemical literacy and chemical culture, is relevant to students' life, and it can cultivate HOCS in students. Finally, we note the expressed reservations and suggestions for improvement.

Keywords: high school chemistry, states-of-matter approach (SOMA), chemical literacy, chemistry textbooks, evaluation of textbooks

BACKGROUND, FRAMEWORK, AND PURPOSE

Chemistry is regarded as a difficult subject for students. The intrinsic nature of the subject and the difficulties associated with the process of human learning are held responsible for this difficulty (Johnstone, 2000). Johnstone has proposed the three-level structure of modern chemistry: the *macro* and tangible level, the *symbolic* and mathematical or *representational* level, and the molecular and invisible or *submicro* level. The psychology for the formation of chemical concepts at the submicro level is quite different from that of the macro/'normal' world.

Chemistry, as an upper-secondary school subject for all, should aim to supply students with chemical literacy and chemical culture, to cultivate higher-order cognitive skills/HOCS (such as critical thinking, problem solving, evaluative thinking and decision making) (Zoller & Tsaparlis, 1997), and to be a useful, interesting, and enjoyable subject. There are various levels and expressions of scientific literacy (Shwartz et al. 2006, and references therein). One categorization distinguishes the following three levels: *practical or functional literacy* is the lowest level, and refers to the ability of a person to function normally in his/her daily life as a consumer of scientific and technological products, such as food, health, and shelter. *Civic* *literacy* (or literacy as power) refers to the ability of a person to participate wisely in a social debate concerning scientific and technologically related issues. Finally, *cultural or ideal literacy* includes an appreciation of the scientific endeavor, and the perception of science as a major intellectual activity.

A chemistry program for all students in the tenth and the eleventh grade (ages 15-17) was proposed in Greece some years ago, and introduced chemistry through the separate study of the three states of matter [the *states-of-matter approach* (SOMA)] (Tsaparlis, 2000). SOMA claims to be consistent not only with a *logical* but also with a *psychological* approach to introductory chemistry. It also was conceived so that to deal with many aspects of scientific and chemical literacy.

There are three major units in the programme, namely: A) *Air, Gases, and the Gaseous State*, (B) *Salt, Salts, and the Solid State*; (C) *Water, Liquids, and the Liquid State*. Following the proposal, a textbook was written that adopted SOMA. The aim of this proposal is to present the book as well as the results of its preliminary evaluation by experienced chemistry teachers.

With the first three major units of SOMA, an original approach to chemistry is attempted through the three states of matter. Table 1 outlines the contents of the book.

Table 1: The contents of the SOMA textbook.

UNIT A: Air, Gases, and the Gaseous State A 1 the atmospheric air A 2 atoms and atomic structure A 3 molecules and molecular structure A 4 the chemical reaction A 5 oxygen and inert gases A 6 the ideal gas and its state equation A 7 hydrocarbons and combustion reactions A 8 air pollution, greenhouse effect, depletion of ozone layer **UNIT B: Salt, Salts, and the Solid State** B 1 salt and the crystal structure B 2 salts, metal oxides, and metal hydroxides B 3 molecular solids B 4 metals B 5 solid waste and its management; recycling of solid materials (metals, glass, paper, plastics)	**UNIT C: Water, Liquids, and the Liquid State** C 1 role of liquid state for life C 2 temperature range for the liquid state C3 intermolecular forces (Van der Waals, London) C 4 water - hydrogen bonding C 5 bromine and mercury: the only liquid elements C 6 organic liquid substances and compounds (diesel fuel, petrol, alcohols, ethers, aldehydes, ketones, acids, esters) C 7 solutions, aqueous solutions of ionic compounds, double displacement reactions molarity C 8 colligative properties of solutions C 9 acids and bases - chemical reactions in aqueous solutions C10 drinking water, water quality, water purification, waste water treatment, water pollution, acid rain

The introduction of the gaseous state first was based on the following facts: (a) being the simplest, it is the best understood by scientists; (b) being macroscopically ‘non-concrete’ for most students (a misconception), it is the most suitable prelude to the study of the invisible submicrocosmos of atoms and molecules; (c) the elements and compounds which are, under usual conditions, in the gaseous state have small and simple molecules [we work with only few non-metals (H, O, N, halogens, and noble gases), and compounds (H_2O, O_3, NH_3, NO_x, CO, CO_2, gaseous hydrocarbons, H_2S, SO_2, HCl)]; (d) we start with the covalent bond (Johnstone, 2000; Johnstone, Morrison, & Reid, 1981); neither ions nor the ionic bond are necessary (the ionic bond and the periodic table are introduced in the unit of solids); in the case of the ideal gas, intermolecular forces are absent (but mention of real gases should be made); (e) the study of organic compounds is introduced early (Johnstone, 2000; Johnstone, Morrison, & Reid, 1981). In this way, some integration of inorganic and organic chemistry is achieved. For more information about *SOMA*, see Tsaparlis (2000).

Note that a follow-up course (for the eleventh grade) completes the "*Chemistry for General Education*" course. This course includes the following chapters: (1) overview of organic chemistry; (2) polymers and plastics; (3) medicines (drugs); (4) biomolecules; (6) food; (7) energy; (8) chemistry, the earth, and the space; (9) chemistry as a continuously developing science. (Chapter 7 covers electrochemistry, nuclear chemistry, and alternative forms of energy.)

A sample page from the book is shown in the appendix. An extended excerpt can be downloaded from the following Internet address:

http://www.parsel.uni-kiel.de/cms/fileadmin/parsel/Material/Ioannina/neu1/Salt_7_-SOMA2.pdf

These texts have been translated from Greek into English by the first author of this article.

METHOD

The role of the curriculum is crucial in the educational systems. Textbooks are written in conformity with the curriculum; hence the role of the textbook is also crucial in the teaching process. It is natural then that the evaluation of textbooks is considered as a necessary condition for the upgrading of the provided quality of teaching.

The SOMA textbook was subjected to a preliminary evaluation by four experienced upper secondary chemistry teachers (plus one university chemistry professor). Three of the teachers were male and one female. One teacher had obtained a graduate diploma in science education (this teacher belonged to the research group of the first author).

When the teachers had completed studying the book, we took structured interviews with them, during which they were asked to answer a number of questions concerning their impression, comments, suggestion for improvements, etc. taking also into account the existing state textbooks for chemistry for general education of tenth and eleventh grades. A second group of questions concerned if the book fulfills the aims of chemical literacy and chemical culture, and if cultivates HOCS in students.

The evaluation is in congruence with the main levels of scientific and chemical literacy (Shwartz et al. 2006). In particular, the above questions can be classified according to the following four dimensions: *Cognitive domain* (learning); *Affective domain* (satisfaction); *Relevance* to students' life (*chemistry and life);* HOCS.

A number of extra questions were obtained from the literature and concerned specific aspects of chemical literacy (Shwartz et al. 2006). These referred to (a) general scientific ideas, (b) features of chemistry (key-ideas).

RESULTS

Cognitive domain (learning)

- The teachers found the book complete, dealing with many matters, and its level was assumed to be advanced (difficult in some cases).
- SOMA was judged very original, having a logical flow of the material.
- All liked the integrated coverage of inorganic, organic, and physical chemistry.

On the other hand, there were some reservations regarding SOMA and/or the book:

- The approach was found good, but quite unusual.
- The book contains a number of difficult concepts (e,g. Millikan's experiment, atomic emission spectra, ΔG, enthalpy, phase diagrams, etc.).
  [*Authors' comment:* Most of these are placed inside boxes, and they are not essential – the teacher can skip this material without damaging the flow of the content. On the other hand, their presence provides for fuller coverage and global knowledge.]
- All agreed that the level of the book is advanced, and that it will be difficult for the average student.

Affective domain (satisfaction)

- In general the evaluators liked the book.
- They all liked its format/lay out.

Relevance to students' life (chemistry and life)

The teachers found very good and complete the practical part of the book (dealing with applications and connections to life). In addition, they were asked to comment on the following features were explicitly stated by the researcher during the interviews with the teachers:

- Importance of chemical language for the explanation of everyday phenomena and their uses by people as consumers of new products and technologies, in decision making, and in their participation in a social discussion relevant to issues where chemistry is involved.
- Relations between development of chemistry and social processes.

[*Authors' comment:* These aspects are served in part by the book. More to this should contribute the follow-up course for the eleventh grade.]

Higher-order cognitive skills

According to the teachers, the book can contribute to the development of these skills. However, the lack of questions and problems was judged as a problem.

[*Authors' comment*: The book needs indeed the inclusion of questions and problems that will contribute to the development of scientific literacy and HOCS.]

Specific questions on chemical literacy

General scientific ideas (these ideas were explicitly stated by the researcher during the interviews with the teachers)*:*

- Chemistry is an experimental science.
- Chemists carry out research and propose theories to explain the world.

These ideas can be achieved with experiments that should be included in the book. According to the teachers, there is need that the book is supplied with a practical part (a laboratory guide).

Features of chemistry (key ideas) served by the book. According to the teachers, the following features are served by the book (these features were explicitly stated by the researcher during the interviews with the teachers):

- Chemistry attempts to explain macroscopic phenomena in terms of the molecular structure of matter.
- Chemistry studies the dynamics of changes and reactions.
- Chemistry studies the energy changes that accompany chemical reactions.
- Chemistry uses a special language – a chemically literate person does not have to know this language, but he/she should be able to appreciate the contribution of the chemical language to the development of this science.
- Chemistry contributes to the understanding and explanation of life on the basis of chemical structure and processes in living organisms.
  [*Authors' comment:* This aspect is covered by the biology course - but also note that a chapter on biomolecules is suggested to be included in the follow-up chemistry course for the eleventh grade.]

Finally, the teachers made suggestions for improvements. We have mentioned already the need for addition of a laboratory guide, and of questions and problems. Most teachers thought that more organic chemistry would be necessary. Organic chemistry is dealt with more systematically and more fully in the proposed follow-up course (see above). Of particular interest is a suggestion by the university professor that the Internet is an endless source of scientific information, facts, and data, hence there is no need to burden anymore modern textbooks with details and facts that can easily be found on the Internet; this will contribute to the drastic shortening of text length.

CONCLUSIONS AND IMPLICATIONS

SOMA combines the logic of chemistry with the psychology of learning (Johnstone, 2000). It could provide scientific and chemical literacy (including chemical culture) to all students, as well as make them appreciate chemistry as an interesting and enjoyable subject, and above all help them to realize its usefulness for their future career and life. We hope that *SOMA* has the potential to give school chemistry a new impetus and status.

SOMA is close to a formalist approach to science teaching. It is possible to combine it, however, with other available context-based material. In this spirit, we have combined SOMA with a recent European Union project, namely '*Popularity and Relevance for Science Education for scientific Literacy*' (PARSEL). PARSEL has developed a number of science modules for secondary education that are available freely on the Internet.[1] Two of the modules, one on carbon dioxide and carbonated beverages and the other on salt, could be used within the *SOMA* units on gases and on solids respectively (Tsaparlis, 2008).[2] A third module on water is under preparation, and that will be suitable to use within the SOMA unit on liquids.

NOTES

[1] The PARSEL Internet site is at the following address: http://www.parsel.uni-kiel.de/cms

[2] The SOMA module on carbonated beverages ("The gas we drink: Carbon dioxide in carbonated beverages") is available in English and in Greek. The module on salt ("Salt: the good, the bad, and the tasty") is available in English, in German, and in Greek. These modules are available at no charge at the following Internet address:

http://www.parsel.uni-kiel.de/cms/index.php?id=modules

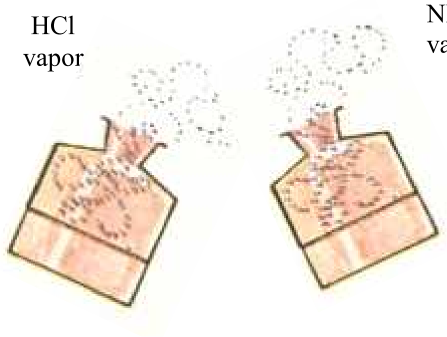
APPENDIX: A sample page from the book from Unit A (Air, Gases, and the Gaseous State)

A 4 CHEMICAL REACTIONS

A 4.1 Chemical changes – Chemical reactions

Often when we bring into close contact between themselves one or more substances (often under the usual conditions of temperature and pressure, but also in different conditions, e.g. higher temperature and/or pressure) one or more changes take place. As a result, one or more new substances are formed, with simultaneous disappearance of part or of the whole of the starting substances. As an example, if we bring into contact gaseous *hydrogen chloride* with gaseous *ammonia*, a new substance is formed, namely the solid *ammonium chloride*:

$$HCl_{(g)} + NH_{3(g)} \rightarrow NH_4Cl_{(s)}$$



The above change is called **chemical change** or **chemical reaction.** A single substance can also undergo a chemical change; for instance, gaseous *hydrogen iodide*, if heated at 550^{o}C in a closed vessel, decomposes into its constituent elements, *hydrogen* and *iodine*:

$$2HI_{(g)} \rightarrow H_{2(g)} + I_{2(g)} \text{ (at 550}^oC)$$

The starting substances are called the **reactants**, while the new substances are called the **products** of the reaction.

There is also the case that a chemical reaction between certain reactants not to take place under usual conditions, but to take place when another substance is present in small amount in the reaction mixture. This extra substance does not change itself during the reaction – it simply makes the reaction possible by its mere presence. As an example, a mixture of oxygen and hydrogen remains unchanged for ever, but reacts vigorously in the presence of platinum (Pt), forming water.

$$2H_{2(g)} + O_{2(g)} \xrightarrow{Pt} 2H_2O_{(l)}$$

In this case, we say that *the platinum **catalyzes** the reaction/**acts catalytically** / is a **catalyst** for the reaction.*

In a chemical reaction, an *interaction* takes place between the molecules of the reactants. The result is that the molecules of the reactants change (by *re-arrangement of the atoms*) into the molecules of the products.

COMPARATIVE EVALUATION OF LOWER-SECONDARY PHYSICS TEXTBOOKS: THE ROLE OF SCIENCE EDUCATION

Georgios Tsaparlis[1], *Georgios Tsoulos*[1], *and Constantinos Kampourakis*[2]
[1] University of Ioannina, Department of Chemistry, Ioannina, Greece
[2] Lykeion of Philippias, Philippias, Greece

Abstract: We examined in actual school practice the effectiveness of an experimental non-standard introductory book to physical science (physics and chemistry) for the seventh grade (first grade of lower secondary school in Greece). The book has been written by science-education researchers, on the basis of principles of science education. In particular, we compared the performance in a relevant test of an experimental group of students (N_1 = 50) who were taught two physics lessons (on the 'force' and on the 'weight of a body') from the above book, with the performance in the same test of a control group of students (N_2 = 50). who were taught the same topics from the standard eighth-grade physics school book. The study was carried out in four eighth-grade classes of two urban lower-secondary Greek schools. The statistical analysis showed that the non-standard book assisted students more in understanding the taught science concepts. However, due to the marginally small sample size and the very limited number of taught topics, the finding should be considered as a preliminary one.

Keywords: physics textbooks, evaluation of textbooks, science education, force, weight

BACKGROUND AND FRAMEWORK

Teaching can be considered a special form of communication and interpersonal relations between the teacher and the students. The role of textbook is crucial in the teaching process. It ensures this communication and contributes more to the growth of interpersonal relations in the classroom than other teaching tools, such as transparencies, experiments, video, PC, etc. (Armbruster & Anderson, 1991).

The evaluation of textbooks is considered as a necessary and sufficient condition for the upgrading of the provided quality of teaching. However, even though the textbook remains the most important teaching tool, it has not gained its proper place either in the relative research literature or in the educational discussions (Bandura, 1986). On the other hand, the results from relative work (Costa et al., 2000) indicate a limited knowledge on the part of the secondary school teachers about the findings of educational research.

Rationale and Purpose

According to the implications of science education research, modern pedagogy should encourage: (a) the active and constructivist teaching and learning; (b) meaningful and conceptual understanding; (c) the development in students of practical abilities; (c) the connection of science with everyday life; (d) a spiral curriculum; (e) the cultivation of higher-order cognitive skills, such as critical thinking. In principle, the application of such instructional methodologies is primarily the job and responsibility of the teacher, and not so much of the textbook. However, to aid the teacher in this job, and considering the limited awarenees of educational research by secondary school teachers (Costa et al., 2000), two of the authors of this article, who are active researchers in science education, decided to prepare the experimental material for this programme in the form of a complete textbook, containing experiments, theory, questions, and problems (Tsaparlis & Kampourakis, 2003).

To our knowledge there is only one international physics book that is based on the learning-by-inquiry model, namely the American textbook "*Physics by Inquiry*", written by L.C. McDermott and her physics education group at the University of Washington (McDermott, 1996). However, we had not consulted and threfore not followed this textbook in writing our own textbook. Our book is entitled "Introduction to physical science" (physics and chemistry) for the 7th Grade" (first grade of lower secondary school in Greece), and is based on principles of science education. Table 1 provides ten basic principles that were adopted in writing the textbook (for details see Tsaparlis & Kampourakis, 2000). The book was written, tested, and evaluated some years ago in the context of the project SEPPE of the Greek Pedagogic Institute. The reader can see an example lesson ("Chemical reactions in aqueous solutions", translated from Greek into English by the first author) in the Supplementary Information/Part 3, to a paper by Tsaparlis et al. (2010) or directly at the following web address:

http://www.rsc.org/suppdata/rp/c0/c005354f/c005354fesi.pdf

In this work, we compare the above book (henceforth called 'experimental book" (EB) against the standard lower-secondary school physics textbook for the 8th grade (school book, SB) (Antoniou et al., 2007). At the outset, we must emphasize that by this work we do not intend to check if the one book is superior to the other; after all, we only used selective topics and a particular test; in addition, due to the relatively small sample size and the very limited number of taught topics, the findings should be considered as preliminary.

Table 1: The ten guiding principles in the writing of the textbook.

1. The spiral curriculum.	6. Scientific rigor - correct use of language.
2. Use of experiments, especially experiments that will be carried out by groups of pupils.	7. Connection of science with everyday life and applications - Development of environmental conscience.
3. Focus on meaningful learning - discouragement of rote learning.	8. Active and inquiry forms of learning.
4. Emphasis on simplicity of phenomena and concepts - priority given to concrete examples – delay of treatment of the abstract concepts of molecules and atoms.	9. Taking into account of students' alternative ideas and misconceptions (constructivist teaching).
5. Delay of representations with chemical formulae and equations.	10. Contribution to students' cognitive development, as well as encouragement of critical thinking.

METHOD

Two Greek urban schools participated in the study (N_1 = 50 N_2 = 50). In each school, the natural class physics teacher taught two lessons (on the 'force' and on the 'weight of a body') from the EB to an intact school class (experimental class, EC); the same teacher taught the same topics from the SB to a different intact class of the same school (control class, CC). The EC and CC were about equivalent, as advised by the class teacher, and as checked by students' average achievement in the first-term physics test. After the teaching, the students of both classes in each school were given the same test for the same period of time (about 20 minutes). Students' answers were graded by the second author. The physics test is shown in the appendix, and consists of three questions. Questions 1 and 2 were taken from the EB (but had been removed from the students' text), while Question 3 was taken from the SB. All questions were demanding and were selected because they tested both for knowledge and conceptual understanding. The small number of questions was directed by the fact that the teachers had only a limited time (20 minutes) to administer the test, because of limited overall available instructional time.

Internal consistency of the test was checked by calculating Cronbach's alpha coefficient. The alpha values were 0.658 for the SB, 0.710 for the EB, and 0.702 for the total student sample. Values form 0.6 to 0.7 are assumed as showing moderate internal consistency, while values higher than 0.7 show higher consistency (Cortina, 1993).

Reliability of the marking was checked by having three experienced teachers first agreeing on a marking scheme and then each one of them marking 15 randomly selected papers. The non-parametric *Spearman* rho correlation coefficient gave values ranging from 0.852 to 0.972. The 15 papers were also marked independently by the researcher who marked all the papers. The correlation coefficient between the researcher's marking and the average marks of the three other markers ranged from 0.849 to 0.983.

Normality of the distributions was checked by means of the Kolmogorov-Smirnov test. It was found that normality was not followed when taking separately each question, but it was followed when taking all questions together. As a consequence, for the comparison of the achievement in all three questions we used the student *t*-test, while for the comparisons of the achievement in each separate question we used the Mann-Whitney non-parametric test.

All statistical calculations were made by using SSSP.

RESULTS

Figure 1 is a box-and-whiskers plot of student performance per question and the average mark of the three questions for the control and the experimental classes. Every box depicts the range of the 50% of middle marks, leaving out the top and bottom 25%. The horizontal line inside a box shows the median. The whiskers show the highest and lowest mark.

Table 2 has the average marks and the corresponding standard deviations for the four classes, the three questions and the average of achievement in the three questions. For question 1 there is a 26.4% difference in favor of the experimental group. For question 2 this difference is only 2.2%, while for question 3 it is 6.8%. Taking the average of the three questions, the experimental group is superior by 11.8%. For the comparison of achievement in the totality of the three questions, the student *t*-test assumed the value of 2.691 ($p = 0.008$), by using both the hypothesis of equal and unequal variance (Table 3). For the comparisons of the achievement in each separate question, the non-parametric Mann-Whitney test gave Z-values equal to 3.586 for question 1 ($p < 0.01$), 0.764 for question 2 ($p > 0.10$), and 3.082 for

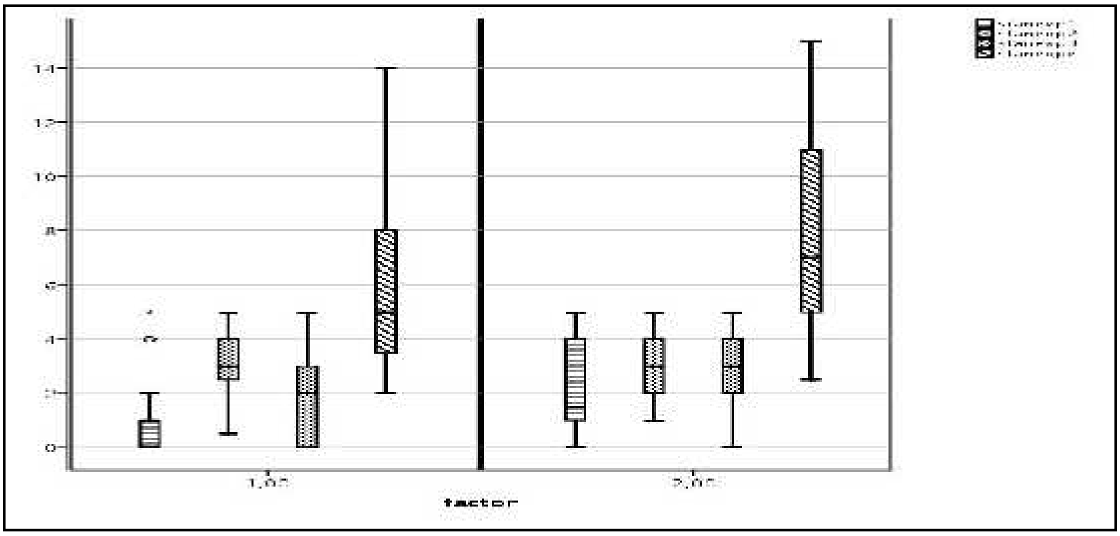


Figure 1. Box-and-whiskers plot of student performance per question and the average mark of the three questions for the control (left-hand side) and the experimental (right hand side) groups.

Table 2: Student achievement per class and per question (mean mark and standards deviations in parentheses (maximum 100). (EC: experimental class; CC: control class)

Class	*Question 1*	*Question 2*	*Question 3*	*Average of three questions*
EC1 (N=25)	40.0 (39.2)	68.0 (24.0)	41.6 (35.6)	49.9(25.9)
EC2 (N=25)	52.8 (37.0)	56.4 (22.8)	47.2 (31.6)	52.1 (22,0)
Total ECs (N=50)	**46.4 (38.2)**	**62.2 (23.8)**	**44.4 (33.4)**	**51.0 (3.60)**
CC1 (N=26)	13.0 (21.8)	65.0 (19.8)	42.4 (30.6)	40.1 (18.2)
CC2 (N=24)	27.6 (32.2)	54.6 (21.8)	32.6 (31.6)	38.2 (21.3)
Total CCs (N=50)	**20.0 (28.0)**	**60.0 (21.2)**	**37.6 (31.2)**	**39.2 (19.6)**

question 3 ($p < 0.01$) (Table 4). In questions 1 and 3, the differences are statistically significant in favor of the experimental classes at the 1% significance level (s.l.). In question 2, the difference is not significant. For the average of the three questions, the difference is significant at the 1% s.l.

DISCUSSION AND IMPLICATIONS

Question 2 asked students to just draw vectors for the exerted forces, but did not require explanations. On the contrary, questions 1 and 3 asked students to explain their answers, hence they were more demanding. This must have contributed to the considerably higher average student marks in question 2.

Table 3: Comparison of performances for the average of the three questions of the experimental and the control group ($N_1 = 50$, $N_2 = 50$) by means of the *t* statistic.

	Levene test for equality of variances		*t-statistic*		
	F	*Sign. level*	*t*	*d.f.*	*Sign. level*
Hypothesis of equal variances	3.945	0.050	2.691	98.00	0.008
Hypothesis of unequal variances			2.691	94.15	0.008

Table 4: Non-parametric Mann-Whitney test for the separate questions.

	Question 1	Question 2	Question 3
Mann-Whitney U	750.5	1207	811
Z	-3,586	-0,301	-3,082
Asymptotic significance level	0,000	0,764	0,002
Statistical significance	p<0,010 (S)	p>0,10 (NS)	p<0,01(S)

Question 1 had an added problem: from the placement of the three boys in the picture many students made the interpretation that the one boy on the right-hand side was pulling against the force of the two other boys. This is supported by the analysis of interviews taken by a number of students.

In the average of the three questions, there is statistically significant superiority of the experimental classes at the 1% significance level. We conclude that the approach to the concepts of force and weight by the experimental book helped students of the experimental classes more than the approach of the school book.

Finally, we must point out a number of limitations of this study. We only used selective topics and a particular test. Also, due to the relatively small sample size and the very limited number of taught topics, the findings should be considered as preliminary ones. Further study is needed, with more topics, more schools, and more teachers. In any case, we must emphasize that we do not claim by any means that the experimental book (of which authors are two of the authors of this article) is superior to the school physics book for the eighth grade. The authors of the school book are certainly capable and enthusiastic teachers and authors and among them are teachers who have studied physics education. In addition, the experimental group was written with a certain approach which has apparently affected the choice of the particular questions used in this study. If we had used a different test the outcome could have been different. We call the readers therefore to take the above limitations into account in interpreting the findings of this study. Further research is needed, which would include more lessons, taught by many teachers and in many schools.

In conclusion, the current aims of science teaching in secondary schools can be served better by textbooks that employ methods and approaches that are supported by the findings of science education research. This requires the use of a multitude of methods and approaches. The experimental book that was tested in this study has adopted such an approach and provided evidence that supports the claim that this book contributed to better achievement in the studied topic and test.

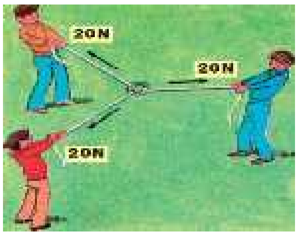
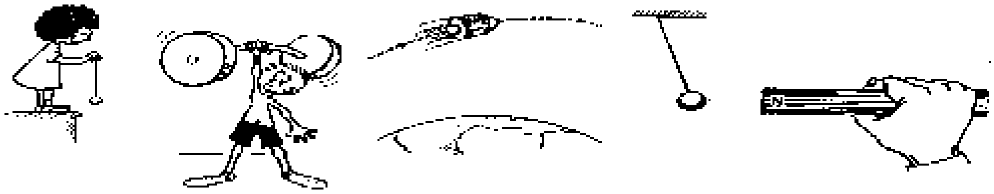
APPENDIX: THE TEST

1. In the figure, each child exerts the same in size force (20 N) on the rope he/she pulls. From the physics point view, are the three forces equal? Explain your answer.



2. In the following pictures, draw the vectors of the forces exerted by: I. The girl's hand on the string. II. The weight-lifter on the weights. III. The earth on the satellite. IV. The magnet on the iron sphere.



3. A schoolmate of yours has this opinion: "A material body has weight when it is on the earth's surface, but it has not weight when it is on the moon's surface". Do you agree? Explain your answer.

WEB-BASED TOOL FOR BASIC CHEMICAL PROBLEM SOLVING IN AN E-LEARNING CONTEXT

José Eduardo Vílchez[1]
[1] Centro de Estudios Superiores Cardenal Spínola (affiliated to the University of Sevilla), Avenida Maimónides s/n, Bormujos, 41930 (Sevilla), Spain

Abstract: In this paper we present a web-based tool which may be used in the didactic treatment of aspects traditionally identified as being a key element in the teaching of chemistry: the solving of simple problems which imply the knowledge of concepts such as mole and amount of substance among others. We have evaluated its use during teacher trainees' first contact with these themes, as a substitute to a classroom session methodology. Good results were obtained. Two homogeneous groups of students with the same level of chemistry knowledge were compared. The group whose learning was based exclusively on the use of the tool without teacher's help, in the end got the same results as the group who received formal instruction from the teacher.

Keywords: Chemical education, E-learning, Web-based tool, Learning object, Problem solving

BACKGROUND, FRAMEWORK, AND PURPOSE

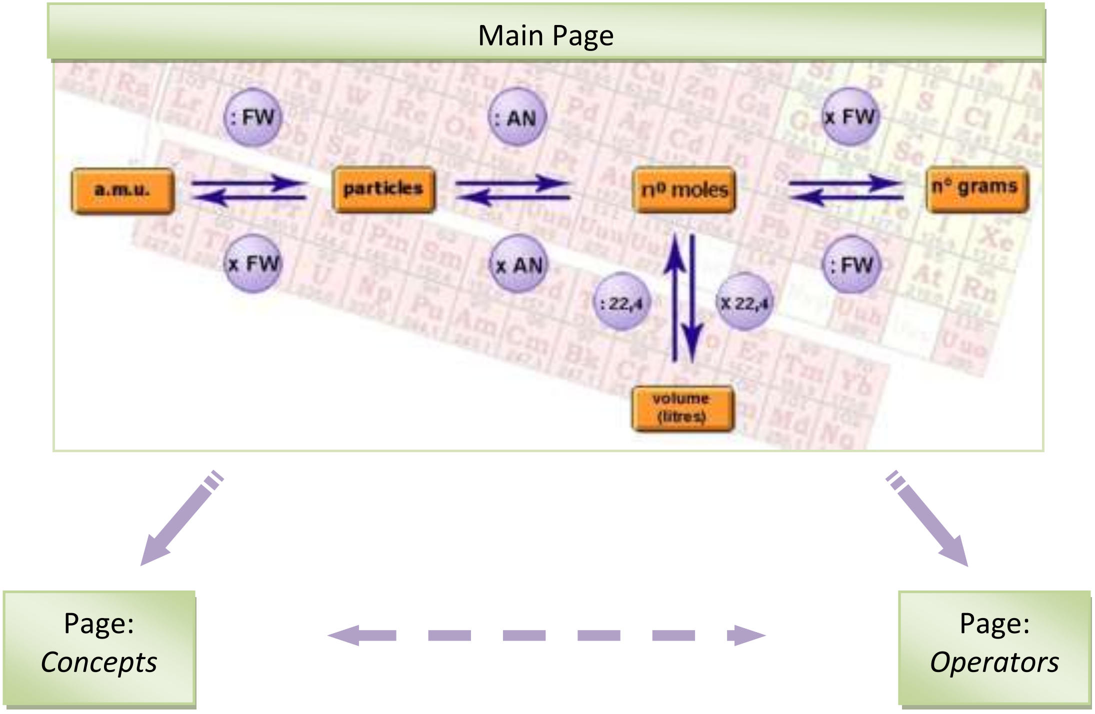
Research in didactics of experimental sciences has traditionally involved the study of the difficulties that certain concepts pose at different educational levels. In the case of teaching chemistry, the key concepts of *mole* and *amount of substance* stand out (e.g., Dierks, 1981; Lybeck et al., 1988; Furió et al., 2002-2006). It seems that the errors in understanding arise from the comparison of the amount of substance with other magnitudes such as mass or volume, or with a number of particles (Avogadro's number). These difficulties are expressed especially in the solving of quantitative problems. Therefore, in many cases the student is incapable of reasoning in terms of proportionality or simple mathematical connections, and learns algorithms or typical problems which he carries out in a repetitive way with little thinking (Gómez-Moliné, 2007; Dahsah and Coll, 2008). Given that generally speaking, overcoming these difficulties depends largely on the direct interaction pupil-teacher, in non-presence teaching contexts the development of materials and methodologies designed to meet that objective is fundamental.

One of the challenges of the application of information and communication technologies (ICT), in the environment of science teaching is the development of adequate teaching tools. Centering on the case of chemistry, the culmination of this evolutionary process is the extended use of hypermedia and of virtual learning environments (e.g., Dori and Barak, 2001; Ardac and Akaygun, 2004; Jiménez and Llitjós, 2008; Maia and Justi, 2009; Own, 2010).

RATIONALE

The tool is a website made up of three multi-linked pages, as is indicated in Figure 1. The main page consists of a concept map in which the main numerical calculations that can be carried out between basic chemical magnitudes, are described. In the nodes of this concept map, concepts such as the number of moles (amount of substance), the mass expressed in grams, the volume in litres, the amount of particles (atoms, molecules, ions….) and the atomic mass units (a.m.u.) appear. These magnitudes are connected by the corresponding operators; formula weight (FW), Avogadro's number (AN) and the coefficient 22.4, which connects the amount of moles and the volume of an ideal gas in standard conditions of pressure and temperature. Each button that appears on the concept map corresponds to a concept or an operator, contains a hyperlink to one of the other two pages, summing up a total of 13 links from the main page (5 with the concepts one and 8 with that of the operators).

Figure 1: Structure of the website *quimicalcul*.



On the page named *concepts*, we include a continuous series of comments for each one of the magnitudes that appear as nodes of the concept map on the *main page*. These comments try to facilitate the understanding of how the concept map works, as well as making the meaning of these concepts more accessible for a beginner student of chemistry.

On the page called *operators*, definitions and comments on the formula weight appear (with atomic and molecular weights integrated within), Avogadro's number (its importance and notes on its historic development), and the coefficient 22.4 (its connection with the ideal gas law). This page also includes on the use of these operators, in the form of small numerical problems already solved, which may be illustrative for the beginner student.

The presentation of the concepts and their connections in the form of just one concept map may bring a series of advantages:

a) In this context, the integration of a series of transformations between magnitudes in which the operators simply multiply or divide may help the student to associate by analogy these calculations with more everyday ones (money, objects which are bought and sold, etc.).

b) Likewise, when they have an overview, the understanding of calculations which require more than one step is made easier. So, for example, the relation between the amount of grams of a substance and the amount of atoms that it contains requires the consideration (explicit or implicit) of two proportions (grams-moles and moles-atoms).

c) The fact that the concept of mole takes up the centre of the concept map, and that the majority of the conversions between magnitudes require "passing through it", is an implicit reinforcement which contributes to the students' understanding of its importance.

However, it would not be satisfactory if learning were limited to correctly carrying out the numerical transformations without a deep understanding of the concepts. So, it is fundamental to have links to the other two pages: *concepts* and *operators*, which would allow frequent consultation of some of the doubtful aspects as well as facilitating access to clarifying examples.

The tool *quimicalcul* has been integrated into a virtual learning environment equipped with the possibilities of the software *moodle* (*ceuandalucia virtual campus*). Therefore, embedded in a content unit, with a group of education students and by means of the platform, so that the teacher carries out his role as guide in learning, is how this tool is adequately used (Figure 2).

Figure 2: Hypertext quimicalcul integrated into the virtual learning environment.

METHODS

Although the preliminary presentation (Vílchez, 2008) and the first details about the efficiency of this tool were moderately positive, we found it essential to collect quantitative data that would contribute to a more objective evaluation. The wide variety and increasing complexity of multimedia resources to teach science make its assessment a task that is not always easy to achieve (Leacock and Nesbit, 2007; Zens et al., 2007; Evans and Leinhardt, 2008). Various approaches may exist according to the interests of different academic communities. In this case, *quimicalcul* is a simple learning object that we have assessed for specific conditions of the educational process.

We have centred on the possibility of using quimicalcul as a substitute to a classroom methodology at the beginning of training in chemistry, in which students come in contact with basic magnitudes and acquire skills in preliminary calculations.

To do this we have used a short, very basic questionnaire consisting of the reasoned solution of 3 small numerical problems which imply the passing of moles to grams (item 1), from grams to moles (item 2) and the passing of grams to molecules (item 3):

If a molecule of gaseous hydrogen (H_2) weighs 2 atomic mass units, consider how many grams a mole makes up.
1) *Calculate the number of grams contained in 5 moles.*
2) *Calculate the number of moles contained in 100 gr.*
3) *Calculate the number of molecules contained in 100 gr.*

Justify the answers.

The questionnaire was given to students enrolled in the course *Natural Sciences and its Didactics* within the Primary Teacher Training program at C.E.S. Cardenal Spínola-CEU (affiliated with the University of Seville-Spain). Students were divided into two groups according to the methodology used. Forming part of one or other group was assigned at random in order to control for variables not related to the intervention:

Group-T (N = 29)**:** In this group students followed a traditional classroom method without using the hypertext *quimicalcul.* The teacher presented the concepts, the connections between magnitudes in an explanatory way and examples on numerical calculations were carried out.

Group-Q (N = 23)**:** Students in this group have only used the tool *quimicalcul*, without the presence of the teacher.

In both groups, the intervention was implemented during a one hour session. The students in each group carried out the proposed exercises of the questionnaire at two time points:

1) After coming into contact for the first time with some basic concepts, but without initiating work with numerical calculations (*Pre-Test*);

2) After the one-hour intervention (*Post-Test*): teacher instruction (*group-T*); familiarization and interaction with *quimicalcul* (*group-Q*).

RESULTS

Each item was marked from 0 to 1, assessing not only the numerical results but also the justifications or lines of argument of the answers. Therefore the global marks of the test range between 0 and 3 points. In *Table 1*, the corresponding data (mean of the total score) are shown as well as the results of the statistical comparison tests used.

According to the results of the Mann-Whitney tests there were no significant differences between *T* and *Q groups* in the total pre-test score ($p > 0.05$). We can therefore conclude, that both groups began at the same level (in any case the means are slightly higher in *group-T*). Across the two groups, a clear improvement in the results of the post-test compared with the pre-test can be observed ($p < 0.05$ in the Wilcoxon signed-rank test).

The comparison between the traditional group and the *quimicalcul* one, after the intervention, also indicates that there were no significant differences between groups' post-test scores, according to the Mann-Whitney test ($p > 0.05$). It is also significant how *group-Q* obtains similar results to those of *group-T* in the post-test, even starting from slightly inferior results in the pre-test.

Table 1: Results of the statistical tests of contrast used.

	Pre-test	***Post-test***	**Wilcoxon signed-rank test**
group-T	Mean = 1.40	Mean = 2.53	Z = -4.21 / p=0.000
group-Q	Mean = 0.97	Mean = 2.56	Z = -3.78 / p=0.000
Mann-Whitney test	U=273.000 / p=0.114	U=276.000 / p=0.243	
Note. As the variables do not fulfil the requirement of normality in their distribution, they are used as statistics of contrast: the Wilcoxon signed-rank test as a substitute of the Related samples T-test and the Mann-Whitney test as a substitute for the Independent samples T-test.			

CONCLUSION AND IMPLICATIONS

We have evaluated the potential of the tool for use in a virtual learning environment like *moodle*, as a substitute for a traditional classroom methodology in solving problems on basic chemical magnitudes in teacher training during the initial phase of the work.

This study shows that *quimicalcul* permits students to get the same results as those achieved with a traditional teaching methodology. This result may be framed within the so called *No Significant Difference Phenomenon* (Russell, 2001), which refers to a type of scientific literature that documents the non existence of significant differences in the results of students who follow alternative education methods. In our case, this “no difference” indicates that *quimicalcul* constitutes a good tool in non face-to-face or distance learning contexts, in the conditions analysed. This aligns with what was found in other investigations which analyse the use of web-based environments as a substitute for traditional teaching methods in science classes at the university level (Lovatt et al., 2007).

As an addition to this work, we are exploring the possibilities of using *quimicalcul* for collaborative learning. As it is embedded in a virtual learning environment it could benefit from the capacities that this offers for interaction among students (forums, wikis).

On a final note, we would like to recommend that teachers to familiarize themselves with this type of tool from their basic training, weighing its advantages and limitations, and thus, appreciating the contexts in which they may be used most favourably.

Abstract: In order to support science learning oriented to conceptual change, we developed a mobile computing system developed by digitising the fortune line method. The theoretical framework for our system is the conceptual ecology model. The system supports the visualisation and sharing of the commitment of numerous learners to multiple ideas.
In addition, we preliminarily introduced the system into Japanese elementary science curricular units and evaluated its possible effect in supporting science learning. Elementary students change their naive concept to a scientific concept after learning in the science curricular unit implemented in the system. The students positively evaluated the system's learning support functions. These results lead us to the conclusion that the system possibly supports science learning oriented to conceptual change.

Keywords: Mobile computing, Conceptual ecology model, Fortune line method

THEORETICAL FRAMEWORK

Conceptual Ecology Model

In science education research, learning science is predominantly viewed as a continual process of conceptual change (e.g., Duschl & Hamilton, 1998). Many science teaching methods and curricula that follow the conceptual change approach place importance on visualisation and the sharing of concepts that individuals carry with them (e.g., Driver, Guesne, & Tiberghien, 1985; Osborne & Freyberg, 1985; West & Pines, 1985).

Various proposals have been made about how to express or describe conceptual change (Chi, Slotta, & de Leeuw, 1994; diSessa, 1993; Vosniadou, 1994). Among these, one of the most widely accepted models by researchers and teachers who aim to promote conceptual change is the conceptual ecology model (Chang, Chang & Tseng, 2010; Posner, Strike, Hewson, & Gertzog, 1982). According to this model, learners' concepts can be described as their ideas and their commitment to these ideas. Therefore, in order to promote conceptual change based on this model, it is essential to allow the visualising and sharing of each learner's multiple ideas regarding a specific learning content and his or her commitment to these ideas.

Although in past studies, various educational technologies have been proposed to support the visualisation of learners' concepts, including text description, semantic networks and imaging (e.g., Linn, 1998; Cañas, Hill, Carff, Suri, Lott, Eskridge, Gómez, Arroyo, & Carvajal, 2004), no technologies have been proposed to support the visualisation of learners' concepts by expressing them as learners' ideas and commitment to them. To enhance curricula and classroom instruction to promote conceptual change, from the viewpoint of educational technology research, it is necessary to develop technologies that use a model well-accepted by researchers and teachers who aim to promote conceptual change as a theoretical base.

The Fortune Line Method as a Representation of Learners' Commitment to Multiple Ideas

What method is employed for visualising and sharing learners' commitment to multiple ideas? We focus on the fortune line method, which was originally a paper-and-pencil method introduced by White & Gunstone (1992) to the field of science education; it is highly regarded for visualising learners' commitment. For example, Kubota (2003) introduced the method in order to probe students' commitments to their supporting theories into the curricular unit 'heat and current' in junior high school. He analysed when their commitments change and showed the method to be very effective and to have powerful functions. Tonishi & Kubota (2004) developed a series of studies to clarify the meaning and effectiveness of the method as a clinical tool for learning in conceptual change-oriented science lessons based on detailed case analysis and suggested that the fortune line method is effective.

However, it is extremely difficult for the method to support numerous learners in sharing their commitment to multiple ideas (the typical class size is 40 in Japanese schools). We assume that by sharing a fortune line drawn to externalise learners' commitment between students or in the entire classroom, we can activate classroom discourse and promote conceptual change in individual students. Based on this assumption, we have attempted to more strongly promote the sharing of commitment through the digitisation of the fortune line method.

MOBILE COMPUTING SYSTEM

Expression of learners' commitment

The learners can input a line by touching the left 'draw the lines' button and touching the input phase (gray-colored zone) on the main screen (**Figure 1**). The user can input different types of lines by touching the middle 'select the pens' button on the main screen and selecting the appropriate pen on the subscreen .

Reference to other learners' commitment

Figure 1: Expression of learners' commitment

Figure 2: Reference on other learners' commitment

The learners can superimpose several different lines of input by several users on their screens by touching the right 'select the lines' button on the main screen (**Figure 2**) and selecting the group member(s) whose line(s) they wishes to view on the subscreen. Using this function, learners can review the differences between their own and others' commitment to multiple ideas, and can discuss their reasons for changes in their commitment.

EVALUATION OF THE SYSTEM: RESEARCH QUESTIONS

The research questions that guide our evaluation study include the following.

(1) Do elementary students change their naive concept to a scientific concept after learning in

the science curricular unit into which the system was introduced?
(2) How do elementary students evaluate the system's learning support functions?

RESEARCH DESIGN AND METHODOLOGY

Participants

The participants in our research were 114 fourth grade students (nine or ten years old) from three classes. They had not used the system or the fortune line method before the research.

Science Curricular Unit

The curricular unit conducted fourteen periods (one period lasted 45 minutes). The learning content was states of matter, and the goal was to change students' naive concept (not all substances exist in the three states (solid, liquid, and gaseous)) to a scientific concept (all substances exist in the three states) through hand-on experiments and discussion.

Viewpoints of Evaluation

(1) Students' Conceptual Change
To answer research question (1), a pre-test and a post-test were conducted before and after the curricular unit. Each question asked whether the substance existed in solid, liquid, and gaseous forms. In each question, students were given options: 'exist', 'do not exist', and 'I have no idea'. It took them approximately 15 minutes to answer the questions. One point was given to students who answered that all states of a substance—solid, liquid, and gas—'exist'. With 17 substances in total, a perfect score was 17.
(2) Evaluation of Learning Support Functions by Students
To answer research question (2), a questionnaire survey of students was conducted after the curricular unit, wherein nine questions were asked about the effectiveness of expression and reference functions of the system for learning support, in other words, items asking students whether learning activities meant to contribute to conceptual change occurred when they used each function of the system. These items were answered using a four-point Likert scale. The survey took approximately 15 minutes.

DATA ANALYSIS AND RESEARCH FINDINGS

Students' Conceptual Change

Figure 4 shows the results of the pre-test and the post-test. While the average score was between 1.5 and 2.5 for the pre-test (class A, 2.3 (SD = 2.0); class B, 1.6 (SD = 1.9); class C, 2.0 (SD = 1.8)), the average score was between 15.0 and 16.5 for the post-test (class A, 15.2 (SD = 2.6); class B, 15.9 (SD = 3.0); class C, 16.1 (SD = 2.5)). Wilcoxon signed-ranks tests were conducted for each score. It was found that the scores of the post-test were significantly higher than those of the pre-test (Z = 5.386 (class A), 5.424 (class B), 5.412 (class C); $p < .01$).

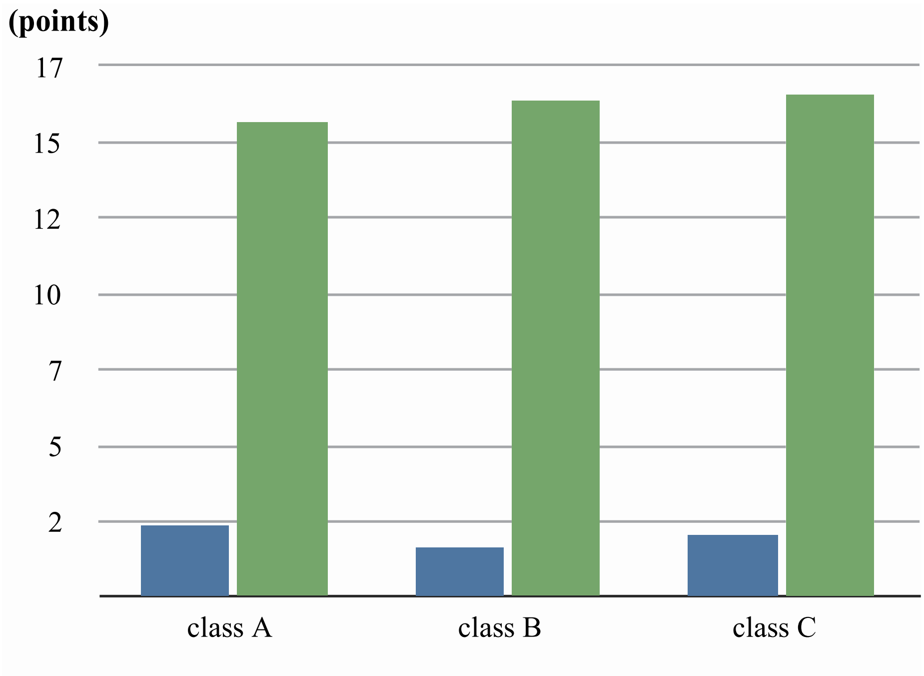

Figure 4: Results of students' conceptual change

Table 1: Results of evaluation of learning support functions by students

	TS	STS	DQTS	DTS
By drawing my line, I understood well which idea I thought was right.	87	22	4	0
By drawing my line, I could explain well which idea I thought was right.	57	43	11	2
By superimposing their lines on my line, I understood well which idea other students thought was right.	98	11	3	1
By superimposing their lines on my line, I understood well the difference between which idea I thought was right and which idea other students thought was right.	93	18	1	1
By superimposing other students' lines on my line, I re-examined my own thoughts about which idea was right.	56	40	11	6
By superimposing other students' lines on my line, I want them to ask questions or comment.	48	42	17	6
By superimposing their lines on my line, active discussions between other students and I began.	52	36	16	9

N=113 (one student absent). TS: Think so; STS: Somewhat think so; DQTS: Don't quite think so; DTS: Don't think so.

Evaluation of Learning Support Functions by Students

Table 1 shows selected question items about the expression and reference functions. Regarding the effectiveness of these functions for learning support, the positive evaluations outnumbered the negative for every item ($p < .01$). Many students acknowledged that the use of expression function supported the reflection of their own conceptual ecologies, and the use of the reference function supported the mutual examination of students' conceptual ecologies in the group discussions.

CONCLUSIONS AND IMPLICATIONS

In this research, we developed a mobile computing system by digitising the fortune line method. In addition, we evaluated a possible effect in supporting science learning. Elementary students changed their naive concept to a scientific concept after learning in the science curricular unit implemented in the system. The students positively evaluated the system's learning support functions. These results lead us to the conclusion that the system possibly supports science learning oriented to conceptual change.

The most important results are that the system supports the visualisation and sharing of the commitment of numerous learners to multiple ideas. This is because providing this support is difficult in the paper-and-pencil method, but is realised by using mobile computing technology (Chan et al., 2006). It is expected that our research will contribute to the increasing popularity of mobile computing technology among the public with regard to the research and teaching practice of science education.

PART 5: NATURE OF SCIENCE, HISTORY, PHILOSOPHY, SOCIOLOGY OF SCIENCE

Co-editors: Laurence Maurines and Andreas Redfors

The implications of nature of science, its history, philosophy, sociology and epistemology, for science education. The significance of models and modelling for science education as reflected in the particular importance attached to the use of metaphors, analogy, visualization, simulations and animations in science.

This part corresponds to strand 5. It contains 24 papers.

TABLE OF CONTENTS OF PART 5

NATURE OF SCIENCE, HISTORY, PHILOSOPHY, SOCIOLOGY OF SCIENCE

INTRODUCTION

These last twenty years, curricula at all three cycles of education have undergone many reforms, both in Europe and elsewhere. The aim is to give all students the opportunity to encompass the scientific and cultural background that allows them to become responsible citizens, capable of understanding and taking action in a world where science and technology occupy a predominant role. Science programs focus on scientific problem solving with methods and skills to be acquired and attitudes such as critical thinking to be internalized. Emphasis is put on knowledge about the nature of science and scientific activity. In particular, students and future citizens are expected to be able to distinguish between what is science and what is not, and develop skills to be able to utilize scientific theories as parts or bases for discussion and explanations of science and technological phenomena met in current and future everyday life. However, these epistemological issues of scientific education, more or less addressed in different countries and curricula, are often implicit in terms of pedagogical goals, content and activities.

The epistemological dimension of science teaching has attracted the attention of many science educators and researchers. Inquiry-based teaching and history and philosophy of science are proposed as strategies to enhance students' views of the nature of science and scientific activity. The field of research presented in this strand explores numerous questions : teaching contents and objectives, students' and teachers' views, e.g. in relation to religious views, the role of Philosophy of Science, teachers' practices such as inquiry-based teaching and role-playing, the significance of models and modelling, strategies to enhance students' and student teachers' and teachers' views of the nature of science, and research-based implementations of innovative pedagogical units which explicitly or implicitly address the NoS question.

THE CONCEPT OF ANALOGUE MODELLING IN GEOLOGY: AN APPROACH TO MOUNTAIN BUILDING

Edite Bolacha[1], Helena Moita de Deus[1] and Paulo Emanuel Fonseca[1,2]
[1]LabGExp- Laboratorio de Geologia Experimental, Centro de Geologia da Faculdade de Ciencias da Universidade de Lisboa, Portugal.
[2]Departamento de Geologia da Faculdade de Ciencias da Universidade de Lisboa, Portugal.

Abstract: Analogue modelling has been used, in geological research, since the XIX century. Today, both in scientific investigation and in teaching, it is viewed as an indispensable tool in the reconstruction of ongoing geological phenomena, as well as it is fundamental to infer geological processes that happened throughout Earth's History.
Considering that analogue modelling can be used as a teaching strategy, when teaching Geology or any other experimental science, it is relevant to define the concept and to reveal its applications and vantages.
As it reconstructs and explains past phenomena through the establishment of cause-effect relations with today's analogue phenomena, analogue modelling became an important methodology in the construction of geological knowledge. This line of thinking has been used, for long, by geologists and, when transferred to the classroom, it can deepen the understanding of Geology. In order to do so, teachers need to plan and test carefully these activities, which usually include other teaching strategies simultaneously. These activities promote student's involvement in their learning, therefore developing multiple skills.
The genesis of a mountain range has always been a central issue for Mankind, in general, and for Geologists, in particular. Therefore, as Geology Theories about this matter have evolved, so have evolved the modelling techniques and, consequently, the teachers should adjust these methodologies in the classroom.
Here is presented a new didactic analogue model of (segments of) mountain building adapted from updated scientific models. It was applied in a Geology class with 12th grade students. This preliminary study showed that analogue modelling helped them to reconstruct their mental models about a contextualized episode of regional Geology.

Keywords: Analogue Modelling, Teaching of Geology, Experimental work, History and Epistemology of Geology, Mountain building.

INTRODUCTION

Materials and equipments used in analogue modelling have been evolving since the XIX century (Oreskes, 2007; Schellart, 2002; Ranalli, 2001). Today this methodology is commonly used in scientific research to simulate geological processes that occurred in well determined time and space units. This is done using dynamic models, built to scale, which allow to the manipulation of several variables, selected according to the object of the investigation (*e.g.* Malavieille, 2010).

Despite its limitations (Deus *et al*., 2011), analogue modelling can easily be applied to the teaching of Geology (either formally or non-formally), because planning a didactic activity requires a certain measure of simplification of the geological phenomena, leading to less variables to control. Visualizing the evolution of the studied geological processes empowers this teaching strategy, making it easy to transfer the studied phenomena to the reality, past or present (*e.g.* CNRS-GeoManips). In all cases, the teacher should be careful regarding the way knowledge is presented, making sure that the students fully understand the limitations of the model at hand, especially by discussing the complexity of the phenomenon investigated. This more systemic view of geological phenomena is attainable if its analogue modelling includes a solid scientific and epistemological approach.

GENESIS OF ANALOGUE MODELLING

James Hall de Dunglass, the founder of Experimental Geology, first performed analogue modelling in the XVIII century. Observations made in the field by Hall, James Hutton and John Playfair, were the basis for modelling experiments. Likewise, today investigators collect data on the field (figure 1) to create accurate geological modelling (Newcomb, 2009).

Fig.1. In Geology data is collected in the field to support Theories and Models.

James Hall was influenced by Hutton's theory which considered that rocks were formed by the solidification of magma and its compression, at great depths. So, Hall designed a series of experiments to test this theory, despite the fact that many other investigators (including Hutton) opposed, arguing that the experiments didn't respect real time and space units in which those phenomena had occurred. Furthermore, they stated that the cause-effect relations established by those experiments were not analogue to the natural phenomena (Oreskes, 2007; Newcomb, 2009). Throughout time, this argument was used by the skeptics of experimental Geology, particularly concerning the construction of models (to scale) of mountains and crust deformation, developed during the XIX century (Oreskes, 2007; Ranalli, 2001). This scientific controversy should be discussed when teaching these phenomena (formally or non-formally), conveying to students a more human view of the scientific activity.

The genesis of a mountain range was a key subject among geologists of the XIX century; so, Hall searched for a way to model that phenomenon. Eventually, he was able to find a mechanism to do it, and this became a prototype to future modelling activities on the XIX and XX centuries. After carefully observing geological structures in the field (mainly folds), Hall used simple materials (first, tissues, and later, clay) to simulate the dynamics that originate a folded mountain range (Newcomb, 2009). He applied geometrical similarities (similar geometry of the structures), kinematics and dynamics – from a qualitative point of view (Ranalli, 2001). The calculations of the model's dimensions were based on the figurative geometry, kinematics and dynamic that characterize the natural phenomenon modelled (*e.g.* Hubbert, 1937). This became a very important approach to modelling because the respect for scale enhances the analogical power of the model created, narrowing the gap between the modelled phenomenon and the natural one. This way the experiment is more reliable and easier to reproduce, therefore closer to what a scientific experiment should be.

IMPORTANCE OF ANALOGUE MODELLING

Taking into consideration all the above as well as the current situation of analogue modelling it is admissible that this is an important tool in the construction of geological knowledge. Then, analogue modelling should be included in the teaching of experimental sciences (Gilbert, 2004), along with other kinds of models, for it promotes the comprehension of natural processes' dynamics and their variables. So, it constitutes good opportunities to enforce the use of experimental teaching approaches (Deus *et al.*, 2011). Moreover, analogue modelling is a dynamic way to simulate natural phenomena, simplifying them and allowing for a deeper understanding. This might require some degree of abstraction, especially if the studied phenomenon establishes an intricate net of relations with other natural phenomena. Recent investigation shows that this can be a challenge if the curriculum presents scientific phenomena in an isolated fashion, with little or no intradisciplinarity (Raia, 2008).

Simulating geological phenomena, which occur in 4 dimensions (3 dimensions of the space plus the time dimension), to scale, allows to a variety of multidisciplinary applications, involving several subjects, both scientific and artistic (Deus *et al.*, 2011). Visualizing scientific processes in 4 dimensions contributes to a better understanding of deep time, which is a difficult, yet very important, concept when educating towards sustainability, putting mankind in a relative position in the timeline of Earth's History. The visualization of phenomena in space's 3 dimensions can develop visual skills like: *i)* observe a 3D image object of a 2D image; *ii)* mentally rotate an object; *iii)* imagine sections of an object that has been cut (Gilbert, 2004). All these skills are very important, not only to study Geology, but also when studying engineering or arts. In short, we can say that analogue modelling plays an important role in Science Teaching because it merges several methodologies used in Science, some of which appear in figure 2.

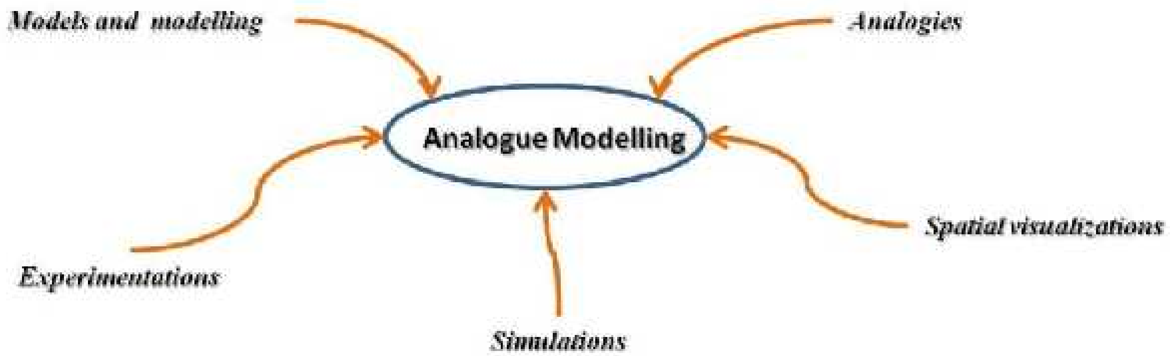

Fig. 2. Examples of methodologies used in Science which are also used in analogue modelling.

Epistemologically, analogue models are a simplified version of updated scientific models, so that they aren't reduced to historical representations of outdated theories or explanations (Gilbert, 2004). When using analogue modelling to present an episode of Geology's History, it should be clearly stated, because it can play an important role in teaching the evolution of geological thinking, as well as to teach current scientific concepts.

MOUNTAIN BUILDING: AN HISTORICAL AS WELL AS AN ACTUAL EXAMPLE

Before Plate Tectonics (1960-1970), many theories came forth to explain the genesis of mountains: from the contractionists (XIX century) to the Theory of the Geosyncline (XX century) (Mattauer, 1980, Oldroyd, 1996; Allegre, 1999). In all these cases, horizontal forces are responsible for the formation of the mountains. What vary, in different theories, are the different sources of those forces (Oreskes, 2007; Oldroyd, 1996).

Hubbert's model (fig. 3) is an example of how historical models can be adapted to current theory. King Hubbert used his sandbox, in 1951, to show some geologic structures and its physical relationships, as well as their causes. Supported by the Theory of Plate Tectonics the same experiment could explain, for example, the relation between the constancy of the Earth's perimeter and the compressive and extensive geological processes.

Fig.3. An episode of Non Formal Education in a Science Centre (Centro Ciencia Viva of Estremoz, University of Evora) with a replica of Hubbert's experiment.

Nowadays, the permanent search for new materials and equipments has led geologists and Geology teachers to the construction of better models. These have been improved by the use of materials with properties that are more analogue to the ones present in natural processes. Therefore, today's teaching models are closer to modern scientific theories.

According to Plate Tectonics, a mountain range develops mainly in a zone where plates converge. To simulate an oceanic plate and a continental border converging (leading to the genesis of a mountain range like Andes), many appropriate analogue models were built and explored, since the 80s of the XX century, by several groups of scientists (Davis *et al*., 1983; Malavieille, 2010; Graveleau & Dominguez, 2008). These are very different from the traditional sandboxes, similar to those used by the pioneers of analogue modelling (*e.g.* Hall, Cadell, Favre referred by Oreskes, 2007), and many times misused in schools to simulate terminal stages of the collision between the plates that originated the Himalayan Range. Taking this into consideration, it is important to study several mountain ranges, to ensure the multiple possible scenarios, therefore developing complex learning skills and avoiding persistent misconceptions.

An alternative modelling activity, is presented here (fig. 4), simulating the genesis of a mountain range, based on several models developed by other investigators (*e.g.* Davis *et al*., 1983; Malavieille, 2010). The model, built at a 1cm:1km scale, and it simulates the genesis of a segment of a mountain range – a accretionary prism, composed by marine sediments, represented by layers of sands with identical internal friction angle and cohesion, therefore analogue to nature. These layers undergo deformation against a backstop, which is analogue to the marine platform or to an already formed section of the mountain, generated by the force inherent to the subducted plate. This force is simulated by a plastic sheet, underlying multiple layers of sand, which moves towards the backstop. Analogue modelling allows varying several parameters, including the height of the layers of sand, the slope of the backstop or the consequences of erosion (Bolacha *et al*., 2011). All together, these convey the idea of a dynamic planet, shaped by multiple variables throughout the Eons of geological time.

Fig. 4. Top picture – early stage of analogue modelling segment of a mountain building. Picture below- the final stage of the same model.

This analogue model was used in a Geology class (12^{th} grade portuguese students) to extrapolate and reconstruct an episode of the geological history of Iberia: the genesis of the accretionary prism of South Portuguese Zone (Ribeiro *et al*., 1979; 2007). Geological maps, texts and images of regional outcrops were used before the analogue modelling activity, in order to help students to construct their mental models (Greca and Moreira, 2000 and references insight) about phenomenon under investigation.

The preliminary results showed that analogue modelling helped the students to reconstruct their mental models about this segment of mountain building along a convergent margin. Before the activity of analogue modelling, most of them had mental models which didn't include the existence of a subduction zone, i.e., closer to the model of the traditional sandbox. Their first mental models about mountain building were consistent with other identified and described by others researchers (*e.g.* Sibley, 2005; Arthurs, 2011). Having the power to induce the reconstruction of the first mental models, analogue modelling is proved to be an important didactic tool. It leads to conceptual change about dynamic processes studied and to the deconstruction of wrong ideas many times included in images and texts in various forms (*e.g.* books, newspapers, and cyberspace).

A more detailed study of this approach in Geology Teaching will be a part of a PhD thesis.

CONCLUSION

Analogue modelling has an important place in Science Teaching because it merges several methodologies characteristic to Science. The use of analogue modelling should be carefully planned taking into consideration the targeted public, so that they can be guided towards the questioning about analogue modelling limitations, namely time, space and the nature of the analogue materials and their rheological behaviour. Furthermore, this teaching strategy should be presented within a theoretical framework, currently accepted by the scientific community, so that it may impart updated knowledge and/or knowledge under construction.

When properly used, analogue modelling can promote conceptual change, leading to a better understanding of present and past geological phenomena.

In future, deeper studies will be conducted in order to confirm the results here presented, that showed that the use of this particular model helped to changed students' mental models about the relevancy of subduction as an important mechanism underlying mountain building. Therefore, their mental models became closer to actual scientific models about mountain building associated with plate convergence.

EVALUATING STUDENT GAINS IN THE PROFILES PROJECT*

Claus Bolte[1], *Sabine Streller*[1]
[1]Freie Universität Berlin (GERMANY)

Abstract: Intervention projects – such as and especially as large as PROFILES – need to clarify the success of their efforts regarding the projects aims. In the case of PROFILES our intervention and efforts are trying to promote - among other objectives the enhancement of students Scientific Literacy.
More specifically, PROFILES aims to promote student gains and thus, the PROFILES project tries to

- balance the attitudes of students toward science and the science education they receive,
- negotiate the meaning and relevance of science education so that science lessons will become more meaningful in eyes of the participating students,
- enhance students intrinsic motivation to learn science and
- foster their abilities and skills especially in the field of learning approaches to science inquiry making justified decisions regarding socio-science and science related issues.

This publication will introduce a theoretically and empirically sound model of teaching and learning science as well as questionnaires and instruments for the investigation of the aims mentioned above. Furthermore we will present and discuss results from different intervention studies obtained by means of the different questionnaires and instruments (mentioned above). The results will be used as examples to offer insights into the potential of the questionnaires and pre-post-intervention-and-control-group design approach. In addition first results from the PROFILES Working Group of the Freie Universitaet Berlin will be presented.

Keywords: IBSE, student gains, Motivational Learning Environment (MoLE) Model, scientific competencies and life skills, project evaluation and questionnaires.

1 INTRODUCTION: PURPOSE OF PROFILES

PROFILES is the acronym for: Professional Reflection-Oriented Focus on Inquiry-based Learning and Education through Science. As mentioned in the PROFILES Project symosium at ESERA 2011 (Bolte et al., accepted; see this proceedings), PROFILES is aiming to implement existing IBSE-focused science teaching materials by means of (long-term) teacher training courses to support teachers' continuous professional development (CPD). The PROFILES consortium members are convinced that the PROFILES CPD programme will convince teachers to take ownership regarding the implementation of evidence based best practice learning environments in order to foster science education and scientific literacy among their students (PROFILES 2010).

Intervention projects such as – and especially such as large as – PROFILES need to clarify the success of their efforts regarding the projects aims. In the case of PROFILES our intervention and efforts are trying to promote - among other objectives (e.g. the increase of teacher ownership) - the enhancement of students' scientific literacy (Gräber & Bolte 1997).

To be more specific, PROFILES aims to promote student gains and by trying to…

(a) balance the attitudes of students toward science and the science education they receive,
(b) negotiate the meaning and relevance of science education so that science lessons will become more meaningful in eyes of the participating students,
(c) enhance students intrinsic motivation to learn science and
(d) foster students abilities, skills and competencies especially in the field of learning approaches to science inquiry making justified decisions regarding everyday life, socio-scientific-science and science related issues.

2 FRAMEWORK AND CONCEPTION OF THE PROFILES PROJECT EVALUATION CONCERNING STUDENT GAINS

"Europe needs more scientists" is the title of the high level group report chaired by M. Rocard and published by the European Commission (2004). But, young adults won't apply for a job in the sciences,

- if their experiences in science are not meaningful,
- if science instruction is less motivating,
- if scientific concepts are considered as irrelevant and
- if persons working in the sciences associate with a negative stereotype (Bertels & Bolte, 2009; 2010; see figure 1).

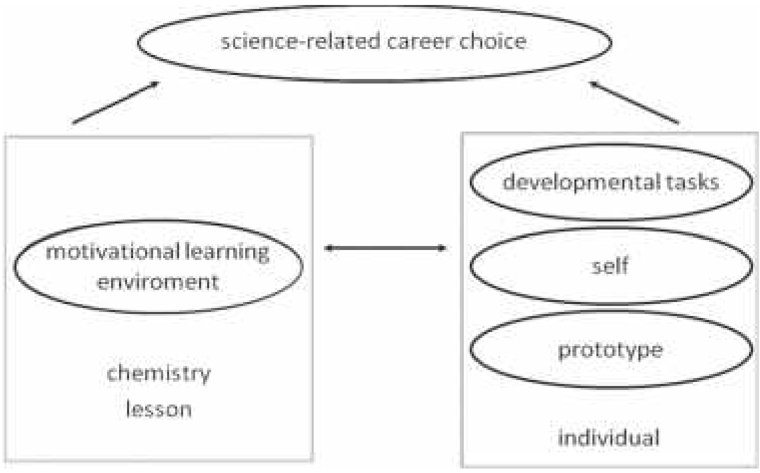

Figure 1: Model of selected variables which effect students' choice of a career in the sciences (according to Bertels & Bolte 2010)

With these aspects in mind, the PROFILES project places a special emphasis on identifying student gains in the affective component – esp. in the (intrinsic) motivational part of science learning and scientific literacy. Above and beyond - but not exclusive - PROFILES also pay attention to specific scientific competencies (e.g. scientific inquiry skills and/or skills of justified and/or informed decision making).

Analysing the outcomes of the PROFILES intervention, linked to the teachers continuous professional development and the promotion of the PROFILES teachers to take ownership for more innovative practices in their science classes, the question of the impact of the project on students is the core part of the PROFILES Work package 7 (see Bolte et al. in this proceedings and/or PROFILES 2010). But evaluating the effectiveness of the PROFILES interventions from a student perspective does not mean that cognitive components are analysed only by means of conventional knowledge tests or that the focus of the evaluation should be on those objectives as they are often described in national education standards. Attention is also paid to evaluate students' motivational gains and the development of their affective skills as well as the students' attitudes related to science, science education and other fields of the sciences (such as (not) choosing a vocational career in a field of the sciences; European Commission, 2004).

Therefore, the PROFILES consortium hypothesises that if science teaching is experienced to be meaningful and profitable, in the students' opinions, (see variable "relevance" in fig. 2), science education and learning science will be strengthened with regards to cognition and contents (see variable "outcomes" in fig. 2) as well as concerning the affective domain of learning science (see variable "satisfaction" in fig. 2). A mixture of cognitive and affective variables which PROFILES will take into consideration are variables such as interest and attitudes towards science, science learning, the image of science and/or of people working in the sciences (also attributed to the variable "outcomes" in the model of fig. 2).

However, the PROFILES consortium agree to the opinion of the European Commission that effective teaching is recognised as a great contribution to a "*generally increased knowledge in the sciences for the young generation*" (FP7-SiS-call, 2009, p. 22). Therefore, science education – as it is promoted by the PROFILES project – can be taken to be successful if the evaluation demonstrates that the *"falling interest in key science topics can be removed and if the lessons foster stimulating intrinsic motivation"* (FP7-SiS-call, 2009, p. 20). High intrinsic motivation in learning science (Streller, 2009; Bolte, 2006), enlightened attitudes towards the sciences (Streller, 2009) and a reflective self-to-prototype-matching concerning the prototype regarding employees in the sciences and one's own self-image (Bolte & Bertels, 2010) are seen as reliable predictors to assess whether an "*increase in the numbers of young people in Europe taking up scientific careers*" (FP7-SiS-call, 2009, p. 22) is likely (Bertels & Bolte, 2009; 2010).

The theoretical framework of the PROFILES student gains evaluation is based on a model of science instruction and the effects of important variables of innovative and motivational learning environments on students' outcome (Bolte, 2006; see figure 2). The core part of this model is related to motivation and interest theories as well as to recommendations from learning environment research (Fraser, 1989; Hoffmann et al., 1998; Gräber, 1998; Deci & Ryan, 2002; Bolte, 2006; Streller, 2009).

The so called MoLE-model (MoLE is the acronym for: Motivational Learning Environment) has been tested by means of LISREL Multi Level Structure Analyses (Koeller & Bolte, 1994). These analyses show that the model is theoretically sound and empirically valid. Furthermore, other analyses reveal that the variables of the MoLE-model and the scales of the questionnaire instrument which is based on this model are highly reliable and also valid regarding the construct validity of our theoretical assumption (Bolte, 2006).

In 2009 Bolte extended his MoLE-model to clarify the questions such as:

(a) 'What is "relevant" from a students' perspective in science lessons?' and
(b) 'How can the variable "outcome" be explained in more detail?'

To analyse the question concerning the variable "relevance" Bertels and Bolte (2009) take the "Theory of Developmental Task" developed by Havighurst (1972) as a basis. This theory was adapted and further and elaborated by Meyer (2006) and Schenk (2005) within their theory of the “learners’ experiences in education and educational development”. Hence, in order to offer more information about the (potential) outcomes, we differentiated this outcome-variable regarding the evaluation of

- “balanced attitudes” (such as the “self-to-prototype-matching” (Hannover & Kessels, 2004) and the science related self-concept of abilities (Hannover, 1998; Bertels & Bolte, 2009; 2010)), as well as the analyses of
- “students competencies” (such as “students’ inquiry qualification” (Erb & Bolte, 2011) and students competencies in making informed and reflective socio-scientific and science related decisions (Bolte, Kirschenmann & Streller, 2009)).

All the mentioned scale have been tested in past studies, and the findings from these empirically based analyses certify all scales (variables) a high level of objectivity and high values of reliability (Cronbach’s alpha; see Bertels & Bolte, 2010; Erb & Bolte, 2011; Bolte, Kirschenmann & Streller, 2009).

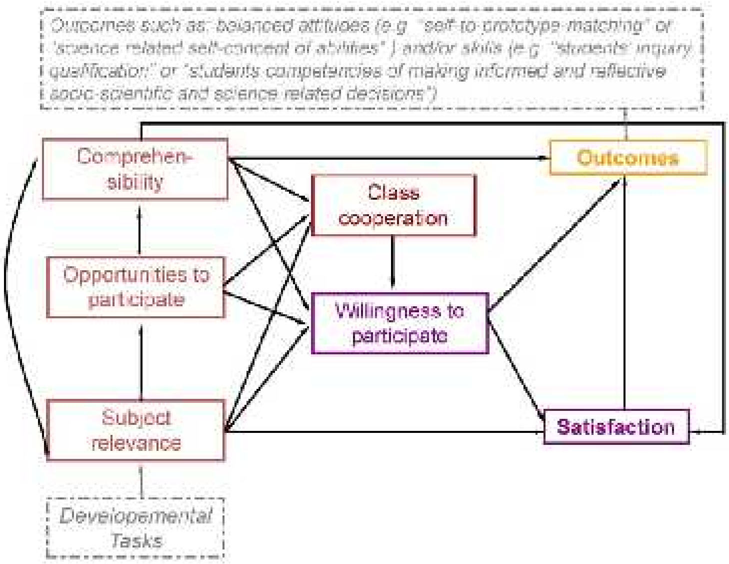

Figure 2: Extended Version of the Motivational Learning Environment Model (according to Bolte 2006)

METHODS

The questionnaires and instruments developed and tested by the leader of the PROFILES Work package 7 and his staff members have been adapted for the PROFILES project to analyze and evaluate the effects of the PROFILES intervention; for example:

- the Motivational Learning Environment Instrument (MoLE; Streller 2009; Bolte 2006);
- the Self-to-Prototype-matching questionnaire (StoP; Bertels & Bolte, 2010);
- a questionnaire assessing the support offered to students dealing with selected developmental tasks of young adults (e.g. occupational orientations, self-orientation, individual reflective value system; Bertels & Bolte, 2010),
- the Inquiry Qualification Questionnaire for the analyses of scientific inquiry skills (IQ^2; Erb & Bolte, 2011), and/or

- the Questionnaire to analyze competencies in the area of making informed and reflective socio-scientific and science related decisions (Bolte, Kirschenmann & Streller, 2009).

The PROFILES project evaluation is designed as pre-post-intervention-and-control-group study. Before the start of the long-term professional development intervention data will be collected from the participating teachers' classes (pre-test; intervention-group) and from classes of teachers who don't participate in the PROFILES teachers continuous professional development programme (control-group). At the end of a school term, both groups will be re-tested with the same instruments again (post-test; in the intervention and the control-group classes).

RESULTS

Results from different intervention studies obtained by means of the different questionnaires and instruments mentioned above are used as examples to offer insights into the potential of the questionnaires and pre-post-intervention-and-control-group design approach. The results and findings from our research can be summarized as follow:

The analyses of our MoLE investigations and especially the comparison of the so called "Wish-to Reality-Differences" points to some (important) reasons why many students end their physics and chemistry classes at the earliest possible grade and why they might not choose a vocational career in the sciences; for example:

- teachers of chemistry and physics often teach *topics which are not relevant to students with respect to their everyday life and/ or to socio-scientific issues*,
- *female students* assess the learning environment in chemistry classes less favorably than male students do,
- *teachers* have problems in anticipating their students' learning environment assessment and need help for the evaluation of the learning climate in their classes,
- *teachers* are not easily inclined to change the subjects of their instruction to topics of increased relevance although their own estimation would support this.

Comparing the self-images and prototypes of German students and of trainees in the vocational field of the sciences we find differences between the self- and the prototype assessments in both groups, but the difference between self-image and prototype of the trainees is much smaller than the differences analyzed in the group of students. All in all, the prototype - the students have - is rather negative, and their self-image and prototype do not match at all. In other words, the negative prototypes students have might actually be one important factor that influences their choice of career.

CONCLUSIONS AND IMPLICATIONS

The use of the instruments we tested and the design of the PROFILES project evaluation we tried out in the past make analyses possible which clarifies the effect(s) of intervention programs, such as the PROFILES project, on student gains. Furthermore, past studies by means of the introduced questionnaires and the chosen evaluation design show that "*various pre-conditions and cultural differences*" (FP7-SiS-call, 2009, p. 20) of students can be taken into consideration. Beside this, by means of the here recommended evaluation approach a "*differentiating [between] girls' and boys' interest*" (FP7-SiS-call, 2009, p. 21) and the specific variables of students' learning outcome becomes possible, reliable and valid.

Abstract: PROFILES (Professional Reflection-Oriented Focus on Inquiry-based Learning and Education through Science) promotes Inquiry-Based Science Education (IBSE) by supporting science teachers to develop more effective ways to teach students, aided by science education actors (stakeholders). The project is based on “teacher partnerships” aiming to implement existing, exemplary, context-led, IBSE-focused, science teaching materials. Long-term teacher training courses, based on challenges of implementing student relevance is set to improve skills in developing creative, scientific problem-solving and socio-scientific related learning environments. A crucial aim is the strong dissemination of evaluated approaches, reactions from different actors (stakeholders) and insights of the PROFILES Project, making use of the Internet, the PROFILES Newsletter and other media.

Keywords: IBSE, continuous professional development (CPD), stakeholder networking, best practice, scientific competencies, life skills, 21st century science, evaluation.

INTRODUCTION: PROFILES BACKGROUND AND PURPOSE

A student motivational, socio-scientific approach to science teaching is promoted by PROFILES currently one of several European FP7 funded projects in the field of “Science in Society” (PROFILES Consortium, 2010; Bolte, et al. 2012; Bolte & the PROFILES Consortium Members, in progress). The PROFILES Consortium, consists of 21 partners from 19 different countries (status quo: May 2011), is promoting IBSE through raising the self-efficacy of science teachers to take ownership of more student-relevant ways of teaching, supported by stakeholders views. The project is grounded on ‘teacher partnerships’ implementing existing, exemplary, context-led, IBSE-focussed, science teaching materials, guided by long-term teacher training, reflecting on challenges identified by participating teachers to raising their skills in developing creative, scientific problem-solving and socio-scientific related learning environments; learning environments which embrace students’ intrinsic motivation to learn science and enhance competencies in undertaking scientific inquiry and socio-scientific decision-making. Measures of success are through determining

(a) the self-efficacy of science teachers in the PROFILES approach and

(b) the attitudinal gains by students towards science and their science education.

The dissemination of PROFILES approaches, reactions from a range of stakeholders and insights from associated research and evaluation form a further key project target. The intended outcome of PROFILES is science education become more meaningful to students, more strongly related to 21st century science, more associated with generic education and especially promoting and enhancing IBSE in school science. In short, the ultimate PROFILES target is to raise teacher's continuous professional development (CPD) and students' scientific literacy.

FRAMEWORK AND CONCEPTION OF THE PROFILES PROJECT

The PROFILES project aims at ensuring the improvement of science education by offering innovative scientific learning opportunities for pre- and in-service teachers, teacher educators, as well as students within school and in non-formal education centres. The PROFILES consortium members are confident to reach this aim by:

- **Establishing close cooperation and networking of the consortium with stakeholders** (see table on WP2 'Support and Co-operation' and WP3 'Stakeholder Views') which provides strong teacher guidance to assist in removing possible obstacles and to build up confidence that the disseminated materials, conceptions and programmes are being enacted, bearing in mind stakeholder views and evaluated, in terms of approval, by stakeholders.
- **Providing teacher training and innovative inquiry-based teaching approaches** to introduce methods of, and teaching modules for, learning and teaching IBSE inspired science, which feature specifically relevance-identified modules (see WP4 'Learning Environments'), and training programmes linked to classroom intervention support. The introduction of PROFILES ideas into pre-service student teacher programmes, by enhancing science educator awareness and interest, is also intended (see WP5 'Teacher Training').
- **Developing strong(er) teacher professionalization and enhancing teacher self-efficacy** through building on an intervention, guiding teacher reflective processes and teacher initiating use-inspired research accomplishments. Additionally professionalization is enhanced through teacher ownership (see WP6 'Teacher Ownership') enacted through adaptation of state-of-the-art teaching modules related to cultural pre-conditions and gender factors, as well as reflective portfolios and action research projects.
- **Evaluating the outcomes of the intervention linked training regarding student gains** (see WP7) **and the promotion of teachers take ownership of more innovative practices**, concerning the students in terms of both attitudes towards the teaching approaches, and their perception of, and interest in science-related learning and careers in the sciences.
- **Disseminating the PROFILES ideas, materials and outcomes** and its potential for greater adoption through establishing teacher networks and interacting with other regional and national networks, as well as networking with other innovative IBSE science teaching projects (see WP8).

The PROFILES educational philosophy is introduced to central stakeholders within the education system of each consortium country via eight inter-dependent work packages (rf. Table 1 and Figure 1). An intended outcome, through continuous professional development (CPD) of science teachers, is to create interactive local, regional, national and Europe-wide teacher networks which positively influence teachers' competence and confidence to promote IBSE-related science teaching and hence raise their self-efficacy to teach in an innovative – more student centered, context-led IBSE – manner, as well as in valuing use-inspired research ideas. This will be evaluated by means of systematic, statistically-based methods, as well as with the help of action research activities.

Work Package	Short title	Coverage
WP 1	Management and evaluation	Project management and external evaluation.
WP 2	Partner co-operation and professional support	Partner professional support to guide PROFILES as per the intended philosophy, goals, outcomes and stakeholder views.
WP 3	Stakeholder involvement and interaction	Bridging the gap between science education researchers, educators, and local actors (stakeholder network and co-operation).
WP 4	Learning Environment	Preparing focus of teacher training materials and identification of IBSE related teaching modules plus their modification and enhancement, based on evaluative feedback and involvement of additional teachers in PROFILES.
WP 5	Teacher Training and Intervention	Planning and Implementation of the (longitudinal) teacher training programme and inter-related teacher interventions.
WP 6	Teacher Ownership	Building on WP5 and reflecting and evaluating the effectiveness and impact of the (longitudinal) teacher training programme with special emphasis on teacher ownership and reflective practices.
WP 7	Student Gains	Evaluating the effectiveness and impact of the teacher training programme/intervention and development of teacher ownership by focusing on student outcomes.
WP 8	Dissemination and Networking	Dissemination at a national, international and worldwide level and establishment of a PROFILES teacher network interrelated to other teacher networks operating at a local, regional, national or Europe-wide scale.

Table 1. Work packages of the PROFILES Project.

Within this intended outcome, and by means of a (long term) teacher continuous professional development (linked and supported by stakeholders) a further key target of PROFILES is to convince teachers that the methods they have studied within the PROFILES programme and tried out during the PROFILES classroom interventions in their science classes will, and can, strongly improve the quality of their own science teaching.

Furthermore, teachers - especially those who participate in the PROFILES longitudinal CPD programme – will become convinced of the need for change in conventional practice. The new viewpoints they have learned in the PROFILES teacher meetings they will discuss with their colleagues; especially the need to interact and to seek for further support by networking with other colleagues (e.g. colleagues of other subjects in their schools, or from 'nearby schools' etc.). Beside this, the PROFILES Consortium expects that the teachers, participating in the PROFILES programme, will be motivated to disseminate their new experiences and the PROFILES IBSE teaching and learning materials through informal and/or formal teacher forums. This will be encouraged both through activities organized by the Consortium partners (e.g. via the PROFILES websites and dissemination network) and by follow-up training courses and informal teacher meetings after the longitudinal teacher CPD programmes at a regional, national and Europe-wide level.

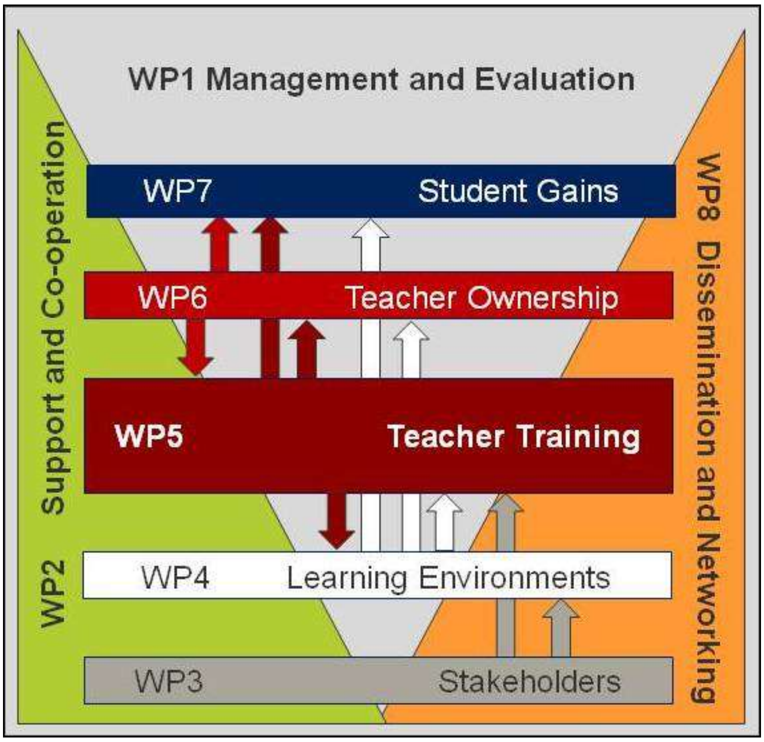

Figure 1. Interdependencies of the PROFILES Project's Work packages

A reflective impact component, first guided by the consortium partners, but later by specific teachers (referred to as 'lead teachers'), is designed to follow-on from the initial training and intervention to raise teachers estimation of responsibility for self-evaluating approaches to analyse students' enhancement of scientific literacy in the participants' schools and/or classes of teachers' special interest groups. These aspects, linked to teachers' self-efficacy, will motivate PROFILES teachers to evaluate their own professional developments as well as guide other colleagues in investigating the success of their teaching; for example by means of action research methods. Professional attitudes like these, we term "teacher ownership".

Confidence that the objectives of the PROFILES Project - the effective and sustainable improvement of teaching through the promotion of self efficacy and teacher ownership - will be reached, is strengthened through evaluation, by both formal and summative assessment. Our evaluation will focus on students' cognitive and affective learning and also on the teaching methods, approaches and materials used within the PROFILES intervention lessons. By means of the PROFILES evaluation it is intended to indicate where improvement is justified and where additional efforts are necessary to improve IBSE to meet stakeholder wishes, as well as teachers and students needs.

From the initiation of the project in December 2010, the PROFILES Consortium emphasises the dissemination of products, experiences and evidence-based outcomes of the project; starting with specific national PROFILES websites in each consortium partner's language and by encompassing the international PROFILES platform (www.profiles-project.eu). But realising that dissemination by partners alone is insufficient, further efforts are included by the PROFILES Consortium to support teachers and stakeholders in general, to appreciate the project and its developments (e.g. by means of strengthened teacher networks and their networking). Through these efforts and interacting with other teacher networks, links are widened, ideas of IBSE are disseminated and teacher-teacher interaction enhanced across borders (insofar as language aspects permit).

Our first steps in dissemination have been taken by presenting the PROFILES Project and its coordinating and supporting actions at international conferences (e.g. Scientix 2011 in Brussels, ESERA 2011 in Lyon, and GDCP 2011 in Oldenburg). A key future event through which it is possible to interact with the PROFILES project and its consortium members, teachers and stakeholders, will take place in Berlin 2012 from the 24th to 26th September, 2012. Those interested to meet PROFILES and the PROFILES actors are invited to participate in this, the 1st International PROFILES Conference on Stakeholders Views and the Enhancement of Inquiry Based Science Education. For more information, please, visit the PROFILES website: www.profiles-project.eu.

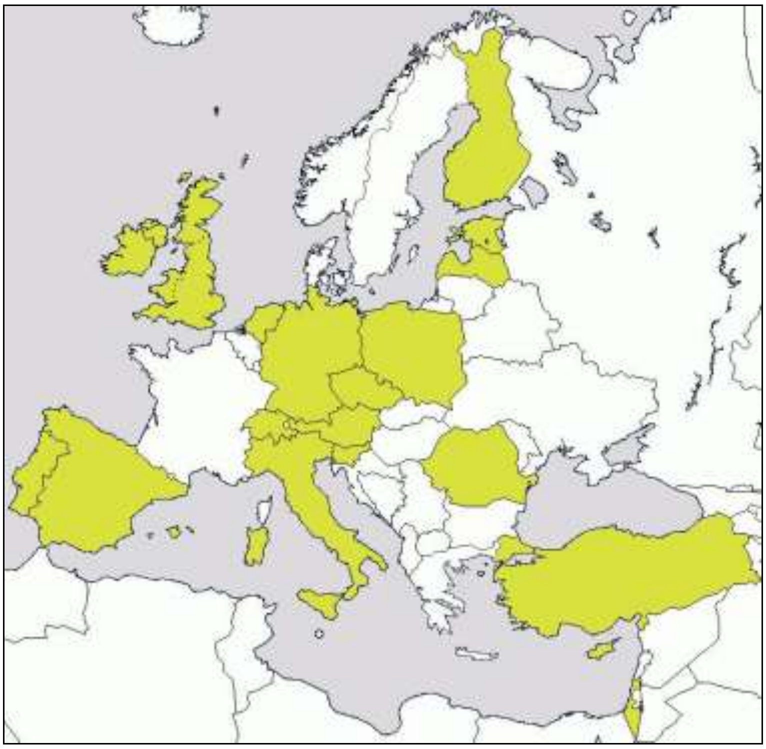

Figure 2. Overview of the countries involved in the PROFILES Project's Consortium*

* The PROFILES Consortium consists of: Freie Universität Berlin (Coordinator, Germany); University of Tartu (Estonia); Weizmann Institute of Science (Israel); Universität Klagenfurt (Austria); Cyprus University of Technology (Cyprus); Masaryk University Brno (Czech Republic); University of Eastern Finland (Finland); University College Cork (Ireland); Universita Politecnica delle Marche (Italy); University of Latvia (Latvia); Utrecht University (Netherlands); University of Maria Curie-Sklodowska (Poland); University of Porto (Portugal); Valahia University Targoviste (Romania); University of Ljubljana (Slovenia); University of Vallalodid (Spain); University of Applied Sciences Northwestern Switzerland (Switzerland); Dokuz Eylul University (Turkey); University of Dundee (UK); University of Bremen (Germany); International Council of Associations for Science Education (ICASE, UK).

Abstract
This study shows the results of the Questionnaire of Opinions on Science, Technology and Society (Spanish acronym, COCTS) applied to students starting and finishing their undergraduate degrees in university careers related to basic science or teaching training in natural sciences in Colombia, Mexico, Argentina, Spain, Portugal and Brazil (Spanish acronym PIEARCTS). The topics evaluated were epistemology, history and internal and external sociology of science (Nature of Science and Technology, NoS&T). Using variational analysis it was stated that the background in science was not a meaningful influence in change of attitude on the NoS&T. Students from Spain and Argentina who had completed studies in science (senior students) had better-informed attitudes than those who just began college (freshman). On the other hand, students from Portugal, Colombia, Mexico and Brazil did not show big differences in attitude.

Keywords**:** Nature of Science. Science, Technology and Society. Science Education. Conceptions assessment.

The Science, Technology and Society (STS) educational movement advocates for a scientific education with a more humanistic approach, including the social dimension of science and technology in science education, taking into consideration ethical values towards science and technology and a democratic point of view to take informed decisions in public matters.

The inclusion of epistemology, history and sociology of science as part of the meta-theoretical discourse has placed science in another context and under another value. According to internal and external factors, science is considered part of a broader cultural context where scientists are product of the same culture. Stated briefly, it is accepted that there is a social contract among society, science and technology, more or less implied, where each supports and builds up the other. The new contextualization of science has produced recent educational research about teachers and student's attitudes thus creating ideas about NoS&T more complex but less absolute.

Studies from Manassero and Vázquez (2002) and particularly Liu and Tsai (2008) examine the differences among different groups of science and non-science students attending two public universities. Generally speaking, students did not have sophisticated beliefs about the epistemology of NoS&T, specifically those referred to theory-laden and cultural dependent aspects of science. Students who were acquiring academic background to become science teachers attained the lowest scores among the groups evaluated (science, non-science and science education students). The bottom line is that science education should be relevant to the complexity of these epistemological beliefs.

Within this framework and the goals of the PIEARCTS project, a comparison of the attitudes held by freshman and senior students of science in some aspects of NoS&T is presented in order to identify relevant differences between those two groups. It is assumed that students who complete their studies in science (seniors) show more sophisticated beliefs than students who begin college (freshman).

METHOD AND INSTRUMENT

According to the PIEARCTS methodology, the COCTS questionnaire (Forms 1 and 2) was applied according to 30 items related to NoS&T. For the comparative analysis, the attitudinal indexes from two types of students were taken into account, through the mean and standard deviation for each question. The analysis stated that the closest the index value to the positive side (+1) the higher the attitude's appropriateness and the more informed. While the closest the index value to the negative side (-1) the lower the attitude's appropriateness, uninformed and naive. To determine significant differences, ANOVA was performed based on the interval $p < 0.01$. The differences weight was established according to its relevance.

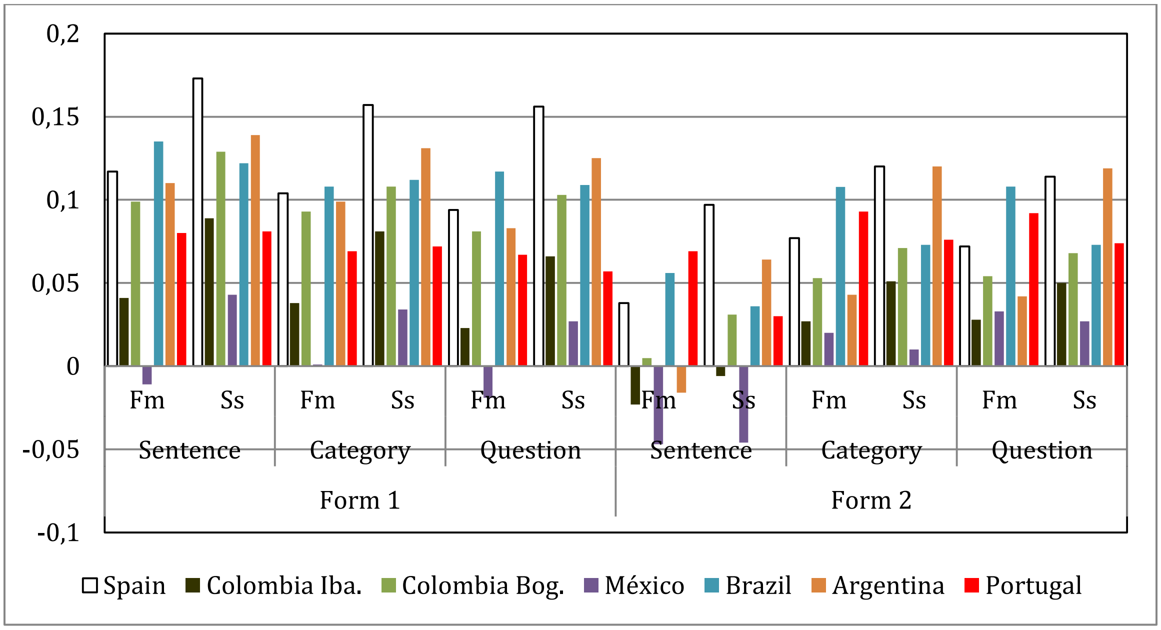
SAMPLE

The total of students answering the COTCS questionnaire in six countries were two thousand three hundred twenty four (2324). One thousand one hundred seventy four (1174) answered Form 1. From this sample, six hundred sixty five (665) were freshman students and five hundred nine (509) where senior students. Form 2 was answered by one thousand one hundred fifty (1150). From this sample, six hundred fourteen (614) were freshman and five hundred thirty six (536) were senior students.

RESULTS

Figure 1 shows the overall averages in sentences, categories and items evaluated in the COCTS (Form 1 and 2) questionnaire by identifying the information level of NoS&T for each group of students (freshman and senior) in the six countries reviewed.

Figure 1. Overall averages for a group of freshman (Fm) and senior students (Ss) of six countries based on sentences, categories and items in Form 1 and 2.



Attitudinal averages do not exceed 0.19. This is statistically interpreted as neutral attitudes towards NoS&T. Students who answered Form 1 in COCTS questionnaire revealed better-informed attitudes than those students who answered Form 2. This means that there are less informed attitudes on issues related to the definition of technology[1], the role of industry, educational institutions[2], social responsibility information, social decisions, gender equity, classification schemes, role of assumptions and epistemological status[3].

[1]For example, students believe that technology is an application of science (Sentence, 10211B). They also think that heavy industry should be moved to underdeveloped countries to save developed countries and future generations of pollution (Sentence, 40161,A).

[2] On the issue related to educational institutions, students do not consider necessary to study science, because not everyone can understand it. They also believe that science is not really necessary for everyone (Sentence, 20511G).

[3] On issues related to the epistemological component of the NoS&T, particularly, the classification schemes and epistemological status of science, students consider that the classifications made by scientists, because they have tested over many years of work (Sentence, 90311A). They also think that scientists discover laws, hypotheses and scientific theories (Sentence, 91011A).

The Spanish and Argentine freshman students have the highest rates in both Form 1 and 2. These students have better-informed attitudes than freshman students, as one would expect. On the other hand, freshman and senior students from Spain, Argentina, Portugal and Brazil show similar values in Form 1.

Based on the issues in Form 2, senior students demonstrate less informed attitudes compared to freshman students. This means that the process of education in science does not imply a better understanding of the NoS&T. According to sentences in Forms 1 and 2 and items in Form 2, Mexican students got the most negatives indexes, indicating misinformed attitudes. Regarding the issues on the questionnaire, Argentinean and Mexican students did not show significant or relevant differences, based on variational analysis. (t> 0.3). This means that science and technology courses do not have an impact on the improvement or acquisition of informed beliefs on NoS&T.

Table No 1 presents the effect size on the issues where the differences between the two groups are significant. Spain has the highest number of significant and relevant differences (9/30). Eight of these are of senior students, among the thirty items assessed.

Table No.1. Significant and relevant differences on items

COUNTRY	FORM 1	EFFECT SIZE	FORM 2	EFFECT SIZE
Spain	F1_40161 Social responsibility contamination.	0,6393	F2_10421 Interdependence quality of life	0,6673
	F1_30111 Interaction STS	0,5206	F2_20511 Educational Institutions	0,6376
	F1_40531 Life welfare	0,3783	F2_60521 Women like men	0,4994
	F1_40221 Moral decisions	0,3621	F2_50111 Union two cultures	0,4251
			F2_40421 Application to daily life	-0,3792
Portugal			F2_90311 Classification schemes	-0,6032
			F2_70211 Scientific decisions	0,3796
			F2_40421 Application to daily life	-0,3138
Colombia (Bogotá)	F1_20141 Government politics of a country	-0.6501	F2_90521 True assumptions	-0.3186
Colombia (Ibagué)	F1_40221 Moral decisions	0.8300	F2_10421 Interdependence quality of life	-0.5036
			F2_20511 Educational Institutions	-0.8782
			F2_40421 Application to daily life	-1.3278
Brazil	F2_70211 Scientific decisions	0,37963	F2_40421 Application to daily life	-0,31389

Only fourteen items out of the thirty evaluated had significant and relevant differences. Freshman students have better information than seniors on topics related to Government politics of a country[4], the relationship of technology in daily life[5], classification schemes, and the nature of the assumptions in science, the interdependence of science and technology and its effect on quality of life.

CONCLUSIONS AND IMPLICATIONS

The analysis of the differences between freshman and seniors students allow us to value the efficiency of college education in science and technology to understanding the NoS&T. The empirical evidence does not enable to establish that such studies improve significantly the understanding of Nos&T. The total number of sentences, categories and items that had relevant positive differences is low when comparing them with the 30 variables analyzed. Some comparisons present significant negative differences, that is to say that the understanding of the NoS&T gets worse over the school years. As a result of a variational analysis, it is stipulated that, based on COCTS, college education in these six countries has no impact on attitudinal change in the relationships to STS. These considerations have to be taken into account as an explicit purpose in college curriculums.

[4] Freshman students, for example, think scientists are influenced by the politics of their country, because governments set policy for awarding research funds to some scientific research projects and not to others (Sentence, 20141B).

[5] Freshman students say the systematic reasoning learned in science classes allows them to solve problems and understand a wide variety of physical events (Sentence, 40421C).

UNDERGRADUATES' BELIEFS ON THE NATURE OF SCIENCE: A COMPARISON BETWEEN SCIENCE AND HUMANITIES

Mayra García-Ruiz[1] y Alejandro Cid del Prado[2]

[1]Universidad Pedagógica Nacional (México)
[2]Universidad Mexicana

Abstract: The purpose of this research was to analyse undergraduate science and humanities students' beliefs on the nature of science and technology (NoST). The study was carried out with 1037 Mexican first graders and senior college students. The instruments used are the Questionnaire of Opinions on Science, Technology and Society two formats (Manassero & Vázquez, 1998). Overall, both groups of students (science and humanities) showed bad informed beliefs of NoST and in several cases, humanities students' showed beliefs more informed than science students, mainly on issues related to science and technology in society, such as social responsibility for pollution, conception of technology, and features of the scientific community. These results show that science students are not receiving enough training in science, as they are not showing a better understanding about NoST. This study could be the basis for design proposals to improve science and technology education.

Keywords: Nature of science, science-technology-society, undergraduate students' beliefs, science and humanities.

BACKGROUND

There are several problems underlying nature of science and technology teaching. One problem stems from the beliefs about S&T, most of students and teachers have uninformed and inappropriate views about science, scientists, scientific method, and scientific work. Furthermore, exists a reductionist view of technology and misunderstanding its relationship with society and environment.

FRAMEWORK

The main goal for science education in the last few decades has been the students developing informed views of nature of science (NOS); a wide research it has been carried out, mainly with basic education students (Abd-El-Khalick & Lederman, 2000; Lederman, 1992). However relatively little attention has been paid to college students' NOS views. Review of the literature has shown different findings about nature of science, some studies have assessed the nature of scientific knowledge views held by college students with different majors, for example Schommer (1993) showed that epistemological views of social science at majors were less sophisticated than those of technological science majors. Other researchers like Jehng, Johnson, and Anderson (1993) found that students in social sciences and humanities were more likely than engineering and business students to view knowledge as uncertain. These findings emphasize the relevance to assess and take into account the beliefs and attitudes about NoST.

RATIONALE

According to some authors (Abd-El-Khalick, 2006; Lederman, 2006; Abd-El-Khalick & Lederman, 2000) exploring the meanings that college science students ascribe to various aspects of NOS is significant because a good understanding of NOS is an essential component of scientific literacy, which is a goal for *all* citizens in participatory democracies (AAAS, 1990; NRC, 1996). In addition, research on teaching and learning about NOS in K-12 and science teacher education indicates that the assumption that students learn about NOS implicitly through engagement in science based activities is not empirically valid (Abd-El-Khalick & Lederman, 2000). That is, NOS should be taught involving to the students in discussions about science activities and their implications for resulting knowledge (Lederman, 2006).

Besides, the college students will join the economic and politically active population of the country.

PURPOSE

Thus, this study was aimed to explore and to compare the beliefs about nature of science and technology and their relations with society and environment, between sciences and humanities Mexican freshmen and senior college students. It was expected that science students would have better understanding about NoST than humanities students.

METHODS

Participants were 1037 Mexican college students in sciences and humanities (60% females and 40% males). Their ages ranged from 18 to 43 years (*M* = 22.7 years, SD = 3.9 years). At the time of the study 495 participants were freshmen and 542 seniors. PIEARCTS project has a common methodology explained elsewhere (Manassero & Vázquez, 1998). The two selected fifteen questions formats of the Questionnaire of Opinions on Science, Technology and Society (COCTS for Spanish acronimus, available on http://www.oei.es/COCTS/) were applied to the participants in the study. The variables analysed were science and humanities majors and undergraduate level (freshmen and seniors).

RESULTS

Overall results showed two important things: 1) the most of the positive indices corresponded to the appropriate phrases and negative indices to the plausible and naïve phrases, both in science and humanities students, and 2) The phrases with the highest positive indices coincided with the classification of the panel of experts who examined these items. This means that participants were able to identify appropriate beliefs that reached a consensus by the scientific community.

Beliefs about NoST in science and humanities freshmen

The comparison between science and humanities' students of the first year showed only one significant difference on the epistemological dimension, specifically in the naïve phrase referred to the scientific models used in research laboratories are copies of reality, *because much scientific evidence has proven them true*; students of both groups had negative indices, science students showed more negative rates (*M*= -.7159 ± SD .338) than humanities students (*M* = -.2698 ± SD.580, p <.0005). These findings showed uninformed beliefs in both groups of students and showed the weaknesses about these issues.

Beliefs about NoST in science and humanities seniors

In the case of seniors (see table 1) both groups of students showed erroneous concepts about technology (phrase F2_10211B_I), they agreed that technology is the application of science, the indices more negatives were presented by science students; regarding to *improve the quality of living, it would be better to spend money on technological research RATHER THAN scientific research* (F2_10421_A_I), science students showed better score than humanities seniors; concerning to the involvement of private companies in science (F2_20211D_P) both groups had negatives scores, but science students presented the most inappropriate answer for the plausible phrase. However, in the case of adequate phrase (F2_20211E_A), science senior students manifested a more informed views; in relation to who must to make the social decisions about scientific issues, just scientist or the decisions must be shared with society *(phrase* F2_C40211B_I *scientists and engineers should decide because they have the knowledge and can make better decisions than government bureaucrats or private companies, both of whom have vested interests)*, both groups had uninformed views, but again science group had more negatives results than humanities group. With respect to application of science and technology knowledge to daily life (F2_40421C_A), both groups of seniors manifested appropriate and positive views and science students had better scores in adequate phrase. Respecting scientific models, both, science students and humanities students said that *scientific models are copies of reality because much scientific evidence has proven them true* (F1_C_90211B_I). But like the freshmen, science seniors showed a more negative average than humanities students. In regard to classification schemes developed by scientists (F2_90311D_A), both groups had positive scores, though science students showed more informed beliefs than humanities students.

Table 1. Beliefs about NoST in science and humanities Students

Significant difference between seniors

Phrases	Students	Mean	Standard deviation	Significance
F2__10211B_I_Technology *(the application of science)*.	Science	-.6610	.4613	.006

models (are copy of the reality *because much scientific evidence has proven them true).*	Humanities	-.2176	.5587	
F2__90311D_A_ Classification schemes *(There are many ways to classify nature, but agreeing on one universal system allows scientists to avoid confusion in their work)*.	Science Humanities	.5862 .3298	.4306 .5988	.003

Freshmen and senior science' beliefs

We found some significant differences between freshmen and senior science students' beliefs. In the adequate phrase referent to *industry should not head science, because if corporations did, corporations would obstruct scientists from investigating important problems which the companies wanted kept quiet; for example, pollution by the corporation*, seniors showed significant higher scores than freshmen; in the phrase related to S&T solving everyday problems (application to daily life, F2_40421_A_I), both science groups had negative indices, but science seniors showed the most negatives. The last sentence in which significant differences were observed pertains to the classification schemes for nature that scientists use (i.e. F2_90311_D_A *There are many ways to classify nature, but agreeing on one universal system allows scientists to avoid confusion in their work)*; in this case both groups had positive views, although seniors performed better than first-years, in the table 2 is shown the effect size of differences.

Table 2. Effect size and significant differences between phrases indices of freshmen and seniors sciences.

Format 2	Effect size	Significance
F2_20211_E_A Industry *(should not head science because if corporations did, corporations would obstruct scientists from investigating important problems which the companies wanted kept quiet; for example, pollution by the corporation).*	0.7913	0.01
F2_40421_A_I Application to daily life *(S&T solving everyday problems)*	1.05	0.000
F2_90311_D_A Classification schemes (*There are many ways to classify nature, but agreeing on one universal system allows scientists to avoid confusion in their work)*.	0.7383	0.008

Humanities students' beliefs

When we analysed the beliefs of humanities students we found a higher number of significant differences between freshmen and seniors, which are shown in table 3.

Table 3. Means, standard deviation and significances among humanities first-year and last-year students related to NoST beliefs.

	First-year students		*Last-year students*		
Phrases	Mean	Std. Dev.	Media	Std. Dev.	Sig.

F2_90111C_I_ Observations	-.3610	.50143	-.1702*	.60521	.004
F2_C_90521A_I_role of assumptions	-.3198	.56997	-.1174*	.66429	.008

*Indicates phrases where seniors got higher scores than first-year ones.

In most of the phrases last-year humanities students showed more favourable beliefs than beginners, including those sentences where both groups had scores either positive or negative, seniors had more positive or less negative scores. For example in the first phrase, F2_C_10421A_I_Interdependence quality of life (i.e. for *improve the quality of living, it would be better to spend money on technological research RATHER THAN scientific research)*, the last-year students had positive and appropriate views, meanwhile the first-year participants had negative indices. The second phrase F1_C_20141I_I is referred to how *Scientists are NOT affected by their country's government policies: because scientific research has nothing to do with politics.* Again humanities seniors had more positive scores. In the next naïve phrase (F1_C_30111G_I) about the interactions among STS, the humanities students disagree with the idea that there is just a light relationship among science and society –as shows this phrase-, they think that exist a mutual interaction between STS, although they are not so sure about the intensity between them, mainly first-year students. With regard to social responsibility with information (F2_C_40131G_I_) that is the social responsibility of the scientist to inform their findings to the general public in a manner that the average citizen can understand (*Scientists should NOT be held responsible since the public often does not seem to care. It's up to the public to learn enough science to understand the reports)*, once more seniors manifested beliefs more informed. Respecting to F1_C_40161A_I_Social responsibility with contamination: Both groups of humanities students had appropriate views and showed social responsibility, they disagree with *the heavy industry should be moved to underdeveloped countries to save others countries, they think that It doesn't matter where industry is located. The effects of pollution are global and moving industry is not a responsible way of solving pollution. We should reduce or eliminate it.* However, even though both groups had positive scores, seniors had better indices. And the phrase F2_C_60521H_I_ of Gender equity *(Women would do science somewhat differently because, by nature or by upbringing, females have different viewpoints, perspectives, imagination, or characteristics - such as patience-)*, both groups of humanities students showed appropriate belief, but first-year students had lowest indices. These results show the effect of training.

The phrase F2_20211C_P_Industry it is noteworthy that freshmen had better scores than seniors. Finally, in the last three phrases showed in the table, like F1_C_40531A_I_Life welfare (referred to *more technology will improve the standard of living of the country, because technology has always improved the standard of living, and there is no reason for it to stop now,* F2_90111C_I_ *Scientific observations will not differ very much even though scientists believe different theories. If the scientists are indeed competent their observations* *will be similar*, and F2_C_90521A_I_ the role of assumptions for the development of the theories or laws that is *assumptions MUST be true in order for science to progress: because correct assumptions are needed for correct theories and laws. Otherwise scientists would waste a lot of time and effort using wrong theories and laws*, the two groups of humanities had negative indices. These negative means corresponded to naïve and plausible phrases and even though in these cases both groups of students show uninformed beliefs, last-year students performed better than beginners.

CONCLUSIONS AND IMPLICATIONS

The results of this study allowed us to identify important NoST teaching and learning elements. This assessment is the basis to design proposals to improve the science and technology education.

In general terms the results showed that college students' beliefs were fragmented and it can be seen a lack of strength in their knowledge. In addition, the most of participants exhibited naïve beliefs and inaccurate understanding about NoST, which confirm previous investigations (Abd-El-Khalick, 2006). The subjects in which college students' had more accurate beliefs were related to social responsibility to pollution and information, and to equality of women and men in science. But they lacked experience in technology concept, scientific community feature and STS interactions.

In this research it was expected that training and experience related to science contributed to a better understanding of the NoST. These results do not support totally this hypothesis. Because working with science and humanities students, we noticed that the humanities students showed more informed and elaborated beliefs than the science ones. Only in a few cases, science students demonstrated better scores than humanities students. We observed naïve beliefs in all groups of students, but contrary to expectations, it was in the science groups where the views resulted less informed and they had lower ability to link science and technology with society. Besides science students had more naïve beliefs overestimating the role of S&T on society and minimizing the role of society on S&T; a possible explanation about these findings could be the influence of previous learning experiences and reflect more entrenched naïve views about S&T. Science students' views of NoST would have been affected by a traditional positivist approach to interpreting what constitutes science. In addition, humanities students' have a strong socio-cultural training by which these students showed a better performance in these aspects. These finding were unexpected, by which we consider that is very important to carrie out a deeply analysis of these results. The significant differences on NoST beliefs among science and humanities' Mexican students proven that students with different major backgrounds have slightly different scientific epistemological beliefs, confirming previous results (Liu & Tsai, 2008) and contrasting with those reported by Schommer (1993), since in our study science students did not have more sophisticated views about science issues. Our findings make evident that the programs of science are not taking into account important aspects of the nature of science, because the senior science students are not showing a better understanding of these issues. It is necessary to address in an explicit and concrete way these contents, as Lederman (2006) has pointed out, the nature of science contents should be presented in a reflective manner and need to be taught as other more traditional cognitive outcomes.

The Mexican science curriculum includes content on NoST such as the study of nature, science and technology, its applications and relations with society, considering benefits and problems in society and the environment. The science students' beliefs indicate a lack of substantive elements as the relationship between socio-economic, political and ethical issues with NoST aspects. On the contrary, in humanities students there were several differences among freshmen and senior, and in most cases seniors showed more informed and appropriated beliefs.

These data can be very useful because, in conformity with Liu & Tsai (2008), in this research we also deemed that understanding the students' epistemological views could offer valuable information for the design of graduate and undergraduate courses to improve students' science epistemological views and provide us with some clear direction in terms of future research and teaching proposals.

Finally, we consider that much more work is needed to develop a better NoST understanding in all college students, not only in science students, because in our society every citizen should be able to make informed decisions about those issues and then to build a better relationship with the environment.

IS THE ATOM REAL OR BUILT? OR IS IT AN INTERMEDIATE BETWEEN THESE TWO? A WITTGENSTEINIAN APPROACH.

Jackson Gois[1,2] and Marcelo Giordan[2]

[1] Department of Chemistry – Universidade Federal do Paraná – Brasil

[2] Faculty of Education – Universidade de São Paulo – Brasil

Abstract: The question about whether the atom is real or built is still among us despite the scientific and philosophical efforts already made. In this work we propose a solution to this question based on the philosophy of Wittgenstein, looking on how we use language. Wittgenstein's thought is considered of crucial importance in twenty century philosophy. Despite the importance of his philosophy, which helps us to think about concepts, language and meaning, nowadays there are few contributions of Wittgenstein's ideas in science education. We challenge the idea of asking questions directly about the atom out of a model and try to put real and building in the right place in scientific practice. We discuss about models, data and natural phenomena, and try to understand them in terms of real and built. Instead of trying to answer this question, we *dissolve* it, remembering what exists and what is built in scientific practice. Wittgenstein's philosophy, as an exercise to a closer look on how we use language, is useful to understand philosophical aspects of chemistry and science education. We must not fear or be angry with either existence or building. It is only necessary to put each one of them in their right place. We think it is an interesting educational solution to this problem, as students will start to see that some usual questions may be illusory.

Keywords: Wittgenstein, Science Teaching, realism, constructivism, philosophy of language

INTRODUCTION

It is quite clear by now that Wittgenstein (2001) wrote about philosophy, more specifically the language illusions that philosophers had been chasing for some centuries thinking it were big truths. Wittgenstein's thought is considered of crucial importance in twenty century philosophy. His contribution has influenced the linguistic turn in philosophy and also many other disciplines. These contributions, like his anti-essencialist approach and his methods of pointing to language illusions where philosophers have been trying to find grounds, are still a challenge to those dedicated to an in deep understanding of his thought. His important philosophy helps us to think about concepts, language and meaning, and nowadays the contributions of Wittgenstein's ideas in Science Education research can be found in influential epistemologies inspired on his philosophy (Wickman and Östman, 2004). The questions about the existence of the atom are important in chemistry courses and teacher training courses. Our main focus is to present a contribution on this subject based on Wittgenstein's philosophy. As well as the philosopher, we want to show that some expressions in Chemistry and Science Education are misleading, and have guided us to ask illusory questions on both fields. In particular, we want to show a philosophical solution, in a wittgensteinian fashion, to the old problem of asking whether atoms are real or built, or even an intermediate between these two positions. We have no intention in finishing this philosophical question, as we are talking to a Science Education community.

It is necessary to observe at first that we, in Science Education research, are not doing any Philosophy of Science research. In fact, in Science Education many historical aspects of Philosophy of Science help us to show the way scientists do science, and these aspects are also interesting to introduce students to important questions in Science Education. Nevertheless, we are always challenged by questions from the Philosophy of Science research field. One of those is the famous question about the existence of the atom. Do atoms exist or are they constructions of our senses? Can we say that atoms are real, for example, in a scientific reality, in opposition to a naïve reality, or the dependence of our senses wouldn't allow us to do such assertions?

The first big congress of chemists took place in Karlsruhe (Nye, 1996). This event gave visibility to Chemistry, and one of the goals was to define general rules to this discipline. One of the main questions was on the divergence of the uses of terms like *atomic weight* and *atomic equivalent*. It was a philosophic question between atomists and anti-atomists, and the background was the existence of the atom. But there was no confrontation between these two groups in that moment, as chemists needed to defend their position against the mecanicist naïve realism of physicists. And this dispute has been renewed in many other flavors, like the dispute between Ostwald's energysm and Boltzmann's realism that ended in 1906 in favor of the late.

More recent disputes on the existence of the atom are about of what representation actually represents, among other topics. Ghins (2010) discusses about the applications that Bas van Fraasen does of Foucault's proposals, when the late challenges the idea that knowledge is representation. Ghins defends a scientific realism, and asserts that models do not represent *completely* natural phenomena. Giere (2006) defends a perspectivist realism, which accord to him would be between realism and constructivism. In his arguments he claims that scientific propositions are neither as objective as objectivist realists want, nor as socially determined as moderate constructivists think. The only fact collectively recognized here is that this surely is a philosophical problem because no more data will solve this old quarrel. In this work we want to analyze the questions, instead of choosing one of the answers.

REAL OR BUILT?

Before our reader accuses us of realism or constructivism, we ask for patience to read our text in full length. We will start with an ordinary question as an example of what we are going to talk, and after that, we will start thinking about our specific subject. Does Santa Claus exist? Of course not, most of human beings would answer. But if we are able to talk about him, so in some sense he exists. Philosophical puzzlement many times starts like this. A wittgensteinian answer to this question would be that we are talking about two similar, but different ways of *existing*. Concepts, models or stories do not exist in the same sense as mountains or natural phenomena. Some philosophers, when asking about this two different existences as if they were one, forget that we, human beings, invented the Santa Claus story, but we did not invent natural phenomena, although we invented ways of thinking and talking about them. And we can use the word *exist* for both, but with different meanings.

From this point we remember a curious fact about the questions of the atom existence: We don't remember someone has ever asked us about the existence of Rutherford's atom, or

Sommerfeld's atom, or any other model's atom. The question about the atom existence is always made as if it was possible to talk seriously about it out of a given model. We forget that it is not possible to ask anything about the atom out of a model. Lets us try, for example, to ask something about the relationship between electrons and the nucleus in an atom. One would immediately ask: in what atomic model? This would be so because, if we think about Dalton's atom, there is no such a relationship, once there is no electron. And these relationships would differ enormously from model to model. It is not possible to ask if the atom, out of a model, is real or built, just because there is no atom out a model. As chemists and physicists most of us keep talking about atoms without specifying a model, just because it is *implicit* in the properties that are on the subject. This leads us to the illusion that it is possible to ask questions directly about the atom.

What is built in science?

We believe no serious researcher think that any atomic model was not built. So, the atom of Rutherford is a model built by us, as well as any other atomic model. We built these models from the data available in the circumstances, and also from any other historic and scientific circumstances. These models were built to explain data, and also to understand better natural phenomena and some of its properties. So, it is an illusion to ask about the existence of the atom, out of a model, because no one doubts that all models were built. It follows that *atoms, in a given model, are built*. We must not feel that scientific knowledge is threatened because we use models as constructions. We just have to put it in the right place.

What is real in science?

At this point maybe the reader is thinking we are going to defend a constructivist approach, but this is not the case. Someone would be inclined to think like this so far in this text because, at the end, we work with science, and there is plenty evidence about the properties of the models we have built. So, something *must* exist! It is not correct to say that atoms exist, because there is no atoms out of a model, but as practitioners of experimental sciences we also don't believe that the world that surrounds us is a mere convention. So, is it possible to speak that something exists? If so, what is this? Is it a reality behind or beyond our senses?

First, is it possible to speak that the data we collect exist, in a strict sense? We don't think so. The data we collect depend upon methods of collecting data, knowledge of how to deal with numbers, charts and other way of representing, and many times it is possible to collect different sets of data from the same natural phenomenon. Our data are also built, in the sense we have to collect them, as well as we have to arrange them in a proper way of representation.

So, are our data mere conventions? Here we have to remember that there are at least two aspects of data. The first one is about the constructs and representations we invented to deal with quantities, and upon what we take data. The second is that when we take data, it is a way to represent some aspects of a phenomenon that exists without human interference. So, about the question of our data being a convention, the answer is *yes* in the sense about the way we write it, and *no* in the sense they mirror some aspects of natural phenomena. These are two different aspects, and sometimes we treat them as if they were just one. We are not defending that data are conventions, but that its representation is a convention. And we are not defending that data is real, but that it represents some aspects of a real phenomenon. The data may be seen as a mirror of some aspects of natural phenomena, but cannot be considered real in a strict sense, like the natural phenomena itself. In any case, we can say that our data is built.

But, does *anything* exist anyway? To understand better about the existence of the world that surrounds us, we have also to remember from what point most of scientific discourse has emerged: understanding natural phenomena. Natural phenomena are the only thing we can say to exist, in a straight sense. No one should doubt about the existence of natural phenomena, as well as no one usually doubts about the existence of the front door of his or her house. It is senseless to believe the existence behind or beyond our senses both to natural phenomena and our door. It is also senseless to doubt their existence. They just exist. So, it should not be necessary to ask if either of them exist. We think, thought, it is important to stress that *the only existence we can talk about, is of natural phenomena*. But the existence of natural phenomena in atomic and molecular level and the evidences about the laws of matter do not give us the right to state that the models we invented exist. Models and data are built. We must not feel that scientific knowledge is threatened because models and data are not real in a strict sense. We just have to put real in the right place, and this place, we believe, are natural phenomena, although data mirrors some aspects of it.

The illusory question

So, the question about the existence or building of atoms is put as if it was two conflicting positions, and you had to commit yourself with one of them. Or worse, maybe there should be an exhaustive mental exercise to find an intermediate position between these two, or even to find a third way of explaining the fact that we build models and are able to talk about natural phenomena. We hold that none of these positions are satisfactory, because in all of them we just forget how we use the words *real* and *built* in everyday life. And if we want to give them new meaning, let us say clearly what meaning is this. It is philosophically misleading to ask a question in a broad sense, e.g. if something is real or built, and expect a specific sense. All we need to do is to remember what is real and what is built in scientific practice, and that it is not possible to talk seriously about atoms without specifying a model.

Conclusions

The question about whether the atom exists or is built is a double illusion. What is built is the atom of a given model and data, and what exists are natural phenomena. So, the atom of, say, Rutherford’s model, is built, although the natural phenomena in atomic and molecular scale, from where both data and model were obtained, is real. The question put forth in the title cannot be answered because it is philosophically misleading and senseless. Instead of trying to answer this question, we tried, in this short work, to *dissolve* it, remembering what exists and what is built in scientific practice. Wittgenstein’s philosophy, as an exercise to a closer look on how we use language, is useful to understand philosophical aspects of chemistry and science education. We must not fear or be angry with either existence or building. It is only necessary to put each one of them in their right place. We think it is an interesting educational solution to this problem, as students will start to see that some usual questions may be illusory.

DETERMINATION OF STUDENTS' MODEL COMPETENCE USING OPEN-ENDED AND HANDS-ON TASKS

Juliane Grünkorn[1], Juliane Hänsch[2], Annette Upmeier zu Belzen[2] & Dirk Krüger[1]
[1] Freie Universität Berlin
[2] Humboldt-Universität zu Berlin

Abstract: Models are an important part of scientific thinking and working methods. Thinking in models enables people to communicate about difficult scientific topics and to reach a consensus. Therefore, scientific thinking and working methods cannot be learned without models (Harrison & Treagust, 2000). However, various studies have shown that most of students` conceptions of models and modeling differ from scientific conceptions (e.g. Grosslight et al., 1991). To describe scientific and everyday conceptions, Upmeier zu Belzen & Krüger (2010) have developed a theoretical structure of model competence. First of all, this theoretical structure needs to be evaluated empirically.

The aim of the presented research projects is to evaluate the theoretical structure using open-ended and hands-on tasks. These different approaches make it possible to cover different facets of model competence concerning thinking in and handling of models (White & Gunstone, 1999).

To achieve this objective, fifteen tested open-ended tasks (Grünkorn et al., 2011) were used and data were collected from a total of 1180 students (grade 7-10). The data were analyzed by qualitative content analysis (Mayring, 2007) to identify different students' conceptions of models and modeling (categories) and to compare them to the theoretical structure. A following study with two evaluated hands-on tasks (Hänsch & Upmeier zu Belzen, 2011) was conducted with four students. 135 student answers given while thinking aloud and during interviews were coded thematically (Hopf, 2001) by assigning the answers to the categories of the open-ended tasks.

The analysis of the student answers shows that the majority of the students' answers are consistent with the theoretical structure. However, the findings revealed that additional facets in the theoretical structure need to be considered. Some categories of the open-ended tasks show hands-on specific expressions.

Keywords: Models, Nature of Science, Model Competence, Open-Ended Tasks, Hands-On Tasks

INTRODUCTION

Models in science are not only resources to teach scientific knowledge, but are also scientific thinking and working tools to generate new knowledge (Mahr, 2009; Upmeier zu Belzen & Krüger, 2010). Various studies have revealed that students reflect little on their thinking in and handling of models and that they are not aware of the role models play in epistemological processes (e.g. Grosslight et al., 1991). PISA 2000 (Artelt et al., 2001) and 2003 (Prenzel et al., 2004) show that German students have difficulties in tasks where the handling of and thinking in models are essential to solving a problem. These results initiated a broad debate about the quality of the German school system (Klieme et al., 2003) whereby normative competencies were defined (KMK, 2005). In biology education, five out of thirteen competencies deal with handling models reflectively in the field of scientific inquiry (KMK, 2005).

To foster students' reflective handling of and thinking in models adequately, scientific and everyday conceptions of models and modeling need to be related and structured theoretically. Upmeier zu Belzen and Krüger (2010) have developed a theoretical structure of model competence describing skills and abilities required for this aim. This structure could serve as a theoretical basis for the development of diagnostic instruments. However, this theoretical structure needs to be tested empirically which is the objective of the presented research projects.

THEORETICAL BACKGROUND

Upmeier zu Belzen and Krüger (2010) designed a theoretical structure of model competence (Table 1) according to empirical studies (Grosslight et al., 1991; Justi & Gilbert, 2003; Crawford & Cullin, 2005) and the view of models in philosophy of science (e.g. Mahr, 2009). It entails two cognitive dimensions: The dimension 'knowledge about models' with the aspects 'nature of models' and 'multiple models' describing individual concepts that are applied when dealing with models. And the dimension 'modeling' with the aspects 'purpose of models', 'testing models', and 'changing models' which describe the handling of models concretely.

Each aspect is further divided into three levels representing different reflection levels. So far, these levels have not been described as developmental levels (Upmeier zu Belzen & Krüger, 2010).

Table 1: "Theoretical structure of model competence (Upmeier zu Belzen & Krüger, 2010)"

Complexity / Aspect	Level I	Level II	Level III
Knowledge about models			
Nature of models	replication of the original	idealized representation of the original	theoretical reconstruction of the original
Multiple models	differences between different model objects	the original allows the creation of different models	different hypotheses about the original
Modeling			
Purpose of models	describing the original	explaining investigated relationships	predicting connections between variables
Testing models	testing the model object itself	comparing the model with the original	testing hypotheses about the original with the model
Changing models	correcting errors in the model object	revising the model due to new findings about the original	revising the model due to falsification of hypotheses about the original with the model

OBJECTIVE

Since this theoretical structure of model competence (Upmeier zu Belzen & Krüger, 2010) has not been empirically tested yet, the aim of the two presented research projects are to evaluate this theoretical structure using open-ended (Grünkorn et al., 2011) and hands-on tasks (Hänsch & Upmeier zu Belzen, 2011).

Both task formats are used to determine different facets of model competence: Open-ended tasks are suitable to determine students' cognitive concrete and general conceptions of models and modeling of a larger sample (Mayer et al., 2008). Hands-on tasks are used to measure – apart from cognitive abilities – procedural knowledge and manual skills (Hamilton et al., 1997). These different approaches make it possible to cover different facets of model competence concerning thinking in and handling of models (White & Gunstone, 1999).

RESEARCH QUESTIONS

The tested open-ended and hands-on tasks were used to evaluate the theoretical structure of model competence (Upmeier zu Belzen & Krüger, 2010). Regarding this aim, the following research questions are posed:

- To what extent are the students' conceptions of models consistent with the theoretical structure of model competence?
- Which additional students' conceptions of models to the theoretical structure of model competence can be identified using open-ended and hands-on tasks?

RESEARCH DESIGN AND METHODS

Open-Ended Tasks

To answer these research questions, 15 open-ended tasks were used and tested in preceding studies for understandability and adequate operationalization to the theoretical structure (Grünkorn et al., 2011). Each open-ended task consists of a short task context, a visualized biological model, and a standardized instruction (Table 2). The tasks were designed in a way that students should be able to give answers at all levels.

Table 2. "Standardized instructions for each aspect"

Dimension	Aspect	Instruction
Knowledge about models	Nature of models	Describe the extent to which this model looks like the original.
	Multiple models	Explain why there are multiple models for one original.
Modeling	Purpose of models	Describe what purpose this model serves.
	Testing models	Explain in detail how people can test if the shown model serves its purpose.
	Changing models	Explain in detail what could have happened so that this model will be changed.

Since one student could not answer all tasks, the task pool was distributed in 35 test booklets (multi-matrix design). The study was conducted with 1180 7th to 10th-grade students aged between 11 and 19 years old to obtain student answers at all three levels. The data were analyzed by qualitative content analysis according to Mayring (2007): In an inductive approach, similar student answers were structured and categories were generated describing different students' conceptions of models and modeling. Subsequently, the categories were assigned to the three levels of the theoretical structure (deductive approach). If a category could not be assigned to the theoretical structure, it was added to the aspect of the theoretical structure. This categorization enabled a detailed description of each aspect.

To evaluate the assigned student answers, additional raters were consulted. The assigned student answers from two raters were compared and differences were discussed until a consensus was reached (Gropengießer, 2001). If a student answered in different categories or levels, all categories and levels were noted.

Hands-On Tasks

Two hands-on tasks were designed based on the process of scientific modeling by Justi and Gilbert (2002) and the theoretical structure of model competence (Upmeier zu Belzen & Krüger, 2010). The structure of hands-on tasks consists of different oral and written parts that encourage students to investigate a biological phenomenon by building their own models. At the beginning of the hands-on tasks, students generate own questions to the presented phenomenon. In order to find hypothesis and plan the examination, important information about the phenomenon is given. Resulting mental models are recorded using a drawing (Gobert & Pallant, 2000). This is followed by the construction of a model with different materials and conclusions about the hypotheses. At the end of each task students are tested whether they can integrate new information about the original in own models. The structure of the hands-on tasks was evaluated by five experts on model competence regarding the adequate operationalization of the theoretical structure and by two linguists regarding the understandability of the tasks. So far, four students (grade 7-10) solved two hands-on tasks in 90 minutes.

Psychomotor skills and verbal aspects of model competence can be determined while solving hands-on-tasks using the multi-method interview. This method consists of three components: interview, thinking aloud and videography (Wilson & Clarke, 2004). Student statements given while thinking aloud and during interviews were coded thematically (Hopf, 2001) by assigning the answers to the categories of the open-ended tasks. The assignments of the student answers to these categories were conducted by two independent coders.

RESULTS

Open-Ended Tasks

Altogether, 38 categories could be described and the majority – 35 categories – could be assigned to the three levels of the theoretical structure of model competence. Table three shows the distribution of the student answers within all aspects of the theoretical structure. If a student answered in different categories or levels, all categories and levels were noted. The category 'not evaluable' represents student answers that did not answer or his/her answer did not correspond to the question.

Table 3. "Distribution of student answers in all aspects"

Aspect, Number of students	Frequency of students' answers in absolute values (%)			
	Not evaluable	Level I	Level II	Level III
Nature of models, n=697	75 (10.8)	478 (68.6)	115 (16.5)	29 (4.2)
Multiple models, n=705	158 (22.4)	369 (52.3)	220 (31.2)	61 (8.7)
Purpose of models, n=707	35 (5.0)	363 (51.3)	337 (47.7)	165 (23.3)
Testing models, n=711	58 (8.2)	219 (30.8)	479 (67.4)	56 (7.9)
Changing models, n=713	118 (16.5)	224 (31.4)	464 (65.1)	4 (0.6)

The percentage distribution of the aspects 'nature of models', 'multiple models', and 'purpose of models' shows that most student answers could be assigned to level I, followed by level II. Level III represents the lowest share. For the aspects 'testing models' and 'changing models' the majority of the students responded at level II, followed by level I. Only a few students gave answers at level III.

Some of the student answers that could not be assigned to the theoretical structure describe three additional perspectives that need to be considered: The aspect ‘multiple models’ is understood as one original is presented by different models. However, several students (n=106) justify the presence of multiple models with different originals or evaluate the shown models for correctness, as exemplified in the following. Those student conceptions were summarized to the category ‘one model for one original’.

Student (Q352): There are different models because there are different types of gullets. Additionally, the shape of the gullet can change after some years.

Student (Q23): I think that two of the three shown models are wrong and that only one model is right.

For the aspects ‘testing models’ (n=6) and ‘changing models’ (n=24) a number of students think it is unnecessary to test a model or think that the model does not change, for instance:

Student (Q71): Why do we need to test this model of a bug? I believe that this is unnecessary.

Student (Q208): In my opinion, this model does not change. The model is final.

Hands-On Tasks

135 student statements from interviews and thinking aloud could be assigned to the categories of the open-ended tasks. Therefore, hands-on tasks can be used for the determination of model competence. In this process, the hands-on tasks confirm the additional categories of the open-ended tasks. Most students make statements on level one and two concerning models as media, as to the open-ended tasks. Additionally, the hands-on tasks lead to reflection of models as tools to generate new knowledge, since many statements can also be assigned to categories on the third level of the theoretical structure. Further, because of the construction of own models, students understand them as idealized representations or theoretical reconstructions in the aspect ‘nature of models’.

A more detailed analysis shows hands-on specific expressions of some open-ended categories. The first relate to the function of the constructed model objects. For example, different functional principles of different model objects are described on the first level of the aspect ‘multiple models’:

Student (Z41): Maybe something works quite differently with a different model. Without this cover, it could fall down.

Another hands-on expression is related to the evaluation of the constructed model objects regarding to the proximity to the original, the achievement of the purpose, creativity, clearness and economy of materials:

Student (A85) I think the model is very clever ... This is also the most logical, because less material had to be used ... The sinking model is clearer than mine.

The following student statement clarifies recognition of a solidarity facet of knowledge acquisition with models, especially on the third level of the aspect ‘multiple models’:

Student (A63): There must be different models for the spinal column because there are people who think differently. Their reasoning will be different to mine. And we help each other through our thinking.

SUMMARY AND CONCLUSIONS

Concerning the percentage distribution of student answers shown in table three, Grosslight et al. (1991) and Crawford and Cullin (2004) note similar findings. Differences can be found for the aspect ‘testing of models’, showing that most students test a model while comparing the model object with the original (level I), whereas in the study of Grosslight et al. (1991) the majority of the students test the model itself to try something out. One possible reason for the prominent conceptions in level I and II of the theoretical structure might be a more frequent use of models as a substitute for the original or as a medium for transmitting information in biology lessons (e.g. Crawford & Cullin, 2004; Van Driel & Verloop, 2002).

Some open-ended task categories show hands-on expressions: For example, many statements relate to the function of constructed model objects because student hypotheses refer to the explanation of functions. Another hands-on expression, different student evaluations of the model objects, can be explained by the individuality of the modeling process (Justi & Gilbert, 2002). In addition, solidarity facets are visible in many student statements. The involvement of students in individual modeling processes leads to the reflection of scientific knowledge. Its social and cultural character (Lederman, 1992) can be deepened using hands-on tasks. Schwarz and White (2005) speak in this context of a metamodeling knowledge.

In both research projects three additional categories ‘one model to one original’, ‘no need for testing a model’, and ‘no need for changing a model’ could be described to the theoretical structure of model competence (Upmeier zu Belzen & Krüger, 2010). Similar results on the conceptions ‘one model to one original’, and ‘no need for changing a model’ are given by Justi and Gilbert (2003) and Crawford and Cullin (2005). In order to foster students’ reflective understanding of models and modeling adequately, it is important to know about these conceptions. Therefore, these perspectives need to be considered and might be added to the theoretical structure of model competence as an additional level.

CREATING A MORE SOPHISTICATED STUDENT VISION OF THE NATURE OF SCIENCE: A SURVEY REPORT

Guerra Andreia[1]; Braga, Marco[1] and Reis, José Claudio[2]
[1]CEFET-RJ – University of Technology – Rio de Janeiro - Brazil
[2]UERJ – State University of Rio de Janeiro - Brazil

Abstract: Science teaching in high schools should stimulate students to understand the philosophical and cultural implications of scientific knowledge. One way to put this principle into practice is to develop curricula using a historical-philosophical approach. However, an investigation of textbooks and syllabuses in Brazil found almost no examples of this approach. This article discusses an educational experience developed in Brazil for students in a high school physics course. The course aimed to introduce a historical-philosophical approach starting with simple student inductive arguments about facts that precede theories. In this course, we introduced new activities and discussed historical-philosophical issues to create exercises incorporating this approach. We also introduced discussions about the worldview of each issue with dialogs about history, economy, arts, and others areas of human culture. Our goal was transforms students' views about science into something more complex. This pedagogical project does not significantly modify the structure of the physics course, but simply introduces conflicts at specific points in the course. The results showed that it is a useful method for including philosophical and historical discussions beyond anecdotal stories about science and scientists to a class.

Keywords: History of Science, Philosophy of science, Nature of Science, historical-philosophical controversies, experimentation.

INTRODUCTION

This research is part of the work developed by Tekne group in Brazil. Our aim is to develop research and pedagogical projects to stimulate students in secondary schools understanding the philosophical and cultural implications of scientific knowledge. The Teknê Group works since 1993 with the historical and philosophical approach in science education throughout the production of support texts.

In order to understand the philosophical and cultural implications of science, the students need to reflect about the process of elaboration of scientific knowledge throughout history (Braga, Guerra & Reis, 2010). Thus it is important to bring discussions about NOS to science's class. As far as we are concerned, the most critical question is: How to promote discussions about science in secondary schools?

This is not a new question. Some researchers have discussed it in last years (McComas, 1998). Some of them defend that the best way to put discussions about NOS in class is to develop activities in science classes which allows students understand the NOS without discussing explicitly aspects of NOS (Abd-El-Khalick & Lederman, 2000). Others defend that teachers have to put science in scrutiny in class, so, in this way, teachers have to develop activities that explicitly discuss NOS (Abd-El-Khalick & Lederman, 2000).

These considerations led us to develop a research with important data for this debate. Therefore, our research aims to answer the following question:

Is the introduction of historical-philosophical issues together with activities putting some element of NOS in scrutiny, a path that leads students to understand the philosophical and cultural implication of science?

To answer this question we've developed and evaluated a Physics course. But before the beginning of the course we had considered some key issues:

1- The scientists path to build knowledge are complex;

2- Scientific knowledge is build "throughout" dialogues among different knowledge.

These issues were confronted with the results of a survey developed previously with 173 students who attended the course. At this moment, the students answered an opened-end questionnaire with four questions. These questions were taken from VNOS-C questionnaire translated into Portuguese (Lederman et al., 2002). The four questions selected were related to experiences, creativity in science and the difference between law and theory. This survey data have shown that 73 % of students believe experimentation is a stage of scientific method that confirms the validation of a hypothesis; 63.6% of students believed that creativity is used only in the building of hypothesis; 14% said that scientists use creativity after data collection (although they pointed that creativity is used only when scientists do not have enough data to explain one phenomenon) and only 5% of them affirmed that creativity is part of all scientists' work. It is important to mention that in the previous survey the students did not give any examples to confirm their ideas.

These considerations led us to concentrate upon the role of experimentation in science. So our aforementioned question has changed for:

> Is the introduction of historical-philosophical issues together with activities that explore some aspects of NOS a path that leads students putting the role of science experimentation in scrutiny?

This question has guided the plan and the evaluation of the Experimentation Physics course. It is important to emphasize that our purpose is not evaluate the students' visions change on science. Our goal is to create a more sophisticated vision of Nature of Science. With these ideas in mind we have planned the course.

THE COURSE

The course was carried on in an 11th grade class with 173 students divided in 5 classes. The students have two physics teacher. One of them was developed his lessons in laboratory and other in classroom. The present course was developed only in the laboratory. The students met the teacher each two weeks. The duration of each meeting was 100 minutes.

The students work in groups. Each group has four or five students. To identify each student and groups we used a code with two characters. The first one indicates the class (A, B, C, D and E). The second one shows the number of student in class.

To evaluate the course we chose a qualitative research approach. Photos and notes were collected during the lessons by teacher and another researcher. It is important to note that the teacher was part of the research team with other researchers.

The theme of the course was Thermodynamics.

We selected a specific historical moment to develop this work. This selection comes from a short book written by Teknê Group about “Lavoisier and the Enlightenment Science” (Braga et al, 2000)

We considered the data of another research develop by Tekne group about the introduction of historical controversies in science lessons to decide which moment to choose (Braga, Guerra, Reis, 2010). The data of this research led us to consider one interesting historical controversy that occurred in the 18th century: the Caloric Theory versus Phlogistic Theory.

How this controversy would contribute to the debate?

This controversy took place in the 18th century, so, it is important to note:

- Newton had unified the terrestrial and celestial Physics. And for many philosophers and scientists the Newtonian Physics model turned to be a good way to explain the world.
- The pharmaceutical and mineral industries growth stimulated the development of experimental science, like chemistry and electricity.
- Chemistry had in its framework elements of alchemy.
- Lavoisier, in France, and Priestley, in England, were investigating gases. They developed experiments to isolate new gases;
- Priestley and Lavoisier rejected metaphysics argument in science. Both believed that experimentation was the best way to build theories;
- Priestley explained his experiments based on the Phlogistic Theory. Lavoisier rejected this theory. For him, was necessary to eliminate the alchemy from chemistry. Therefore, it was necessary to build a new framework for chemistry and a new nomenclature to eliminate the past.

So controversy allows us to discuss with students the context in which Lavoisier and Priestley lived and worked led them to different ways, to different ideas. Because in the dialog of scientific knowledge with cultural context, theories did not determine the results of experiments, neither experiment determines theories (Hacking, 1983).

To put these arguments in evidence, along with the controversy discussion developed by teacher, the students read, at home, a book (Braga et al, 2000) discussing the controversy and in class they conducted some experimental activities that explicitly the difference between law and theory.

The activities:

1- **Solid expansion**. Doing the experiment the students obtain the law of expansion of solids. But it does not explain why the solid expand. So we discuss the difference between why and how.
2- **Calorimetric experiment**. Doing the experiments the students determined the relevant parameters to determine the heating of a body, but it does not explain what is transmitted between the two bodies. So we use this moment to discuss with the

students that with caloric theory and phlogiston theory was possible to explain what is transmitted between the two bodies.

3- In the discussion students showed some discomfort with the narrative of the controversy. They wanted to know who, Lavoisier or Priestley, built the right theory. When the teacher told that both theory are today considered wrong, and that some name gave by Lavoisier to the chemical elements, like oxygen, had a significance which do not make sense today, the students were impressed with these discussions, they claimed by a truth.

   A few students' comments were:

   "experiments should prove which of these two hypotheses was wrong. Scientific knowledge´s based on laws and theories, and theories were accepted by experiments. Rutherford proved his theory about atomic model before set up an experiment to prove it." (C4)
   "the experiments should show which of these two hypotheses is right or wrong" (E34)

4- Given this outcome, after these two activities, and before the controversy narrative end we developed with students two activities that do not have content embedded. We decided to make the aspects of NOS we wanted to discuss with students more explicit.

The first activity was the black box activity; with this activity we discussed the role of models in the scientific knowledge.

With the second activity we put the experimentation in science in scrutiny. The students received a set of wood pieces to build a figure. But with these pieces they could build different figures. So with the same pieces they could build different models, but not any model, because they could not excluded the pieces. The teacher discussed these results and compared them with science experimentation. If the data tell something to scientists, they could not ignore the pieces, but if the data do not answer completely the problem, they have to consider others parameters again.

CONCLUSIONS

After 45 days the students received the four questions that they have answered in the beginning of the course. The results of this survey showed that 62.5 % of students believe that experimentation is a stage of scientific method which confirms the validation of a hypothesis.

"It is the attempt to prove one hypothesis through instruments" (B4).

"It is a fact to be observed in laboratory with a premise, such as the hypothesis test". (D14)

37,5% of students affirm that the creativity is used only in the building of hypothesis.

"Yes. In the hypothesis elaboration, they use imagination and creativity, and after that they could make the experiments". (B5)

"Yes, because they use creativity as a starting point, but always based in scientific observations". (A6)

22.5% the students argued that creativity is part of all scientist´s work. For instance, some of them argue:

“It is something very important, because there are a few obvious things and it is necessary to be open to different opinions “not-so-obvious”. We believe the scientist uses imagination and creativity in all steps, but in some more carefully than others” (A15).

“Yes, in the Project and planning, and after data collection as well. Creativity is needed to create a productive form of data collection and after this data collection to transform the data into ideas. For instance, Galileo turn up the telescope to the sky to visualize something never seen before. Another example is analyzing a ball in movement, it is not only the velocity data collection and its standard deviation, but it is necessary transforming these numbers in an acceleration concept” (E8).

For the difference between law and theory we noted that 27.5% answered the question in the same way that they had answered in the beginning of the course. For this group law is a theory which the scientists had proven with experiments. In the same question, 42.5% argued that theory explain a phenomenon while law describes a phenomenon.

“Yes, when we describe how the things dilate with the variation of temperature we have a law, when we explain this phenomenon with atomic movement we have a theory” (C4).

20% said that law is invariable while theory is variable.

“Theory is an idea accepts by scientists, but always it could be changed. Law could not be changed. Examples: String theory could be change but Gravitation law could not be changed”. (E8)

When we compared the two group of answers and confronted them with the researcher´s notes obtained during the course, we realized that the course have somehow provoked disturbance in the student´s vision of science. In the previous questionnaire the answers were basic without examples that support them. At the end of the survey the answers were more elaborated and the students gave some examples to support their ideas.

In the examples gave by the students something was highlighted for the researchers: 29% of the students who declared that experimentation is a stage of scientific method confirming the validation of a hypothesis used the same example to confirm their ideas. They cited the Brownian movement and the Rutherford experiment as examples to confirm that experimentation is just a way used by scientists to ratify their hypothesis. When we investigated why these groups of students gave the same example, we realized that these were examples that their Physics theory teacher (the one who develops the other three classes) used to prove that the true theory to explain Thermodynamics is the Atomic theory. In an interview with this teacher, he revealed that in beginning of the course he discussed the atomic model, starting by the Greg model and finishing with Rutherford experiment. In his opinion, this is a crucial experiment that confirms the atomic hypotheses. After that, he discussed with the students the Brownian movement and used it like a macroscopic experimentation to prove the existence of a microscope element, the atom.

These results showed us two things. First one the introduction of historical-philosophical issues together with activities that explore some aspects of NOS in scrutiny is a path that leads students to understand the philosophical and cultural implication of science. The historical examples seemed not be sufficient to put science in scrutiny.

It is not easy to discuss NOS. The students have some ideas about NOS that they build throughout their schooling and these ideas are everyday reinforced by teachers. This conclusion does not mean that it is impossible to provoke disturbance in the NOS visions in the students. Our research showed us that the lessons described here were an opportunity for those students to reflect about science. They did not change their vision from a suppose naïve idea to an adequate one but their vision became somehow more complex.

MISSING LINKS IN THE EXPERIMENTAL WORK: STUDENTS' ACTIONS AND REASONING ON MEASUREMENT AND UNCERTAINTY

Susanne Heinicke[1] *und Falk Riess*[1]
[1] University of Oldenburg, Germany

Abstract: Over the past 25 years, a number of studies have offered valuable insight into the concepts of students concerning the handling of measurement data and uncertainty. They helped introduce a number of new approaches to the introductory laboratory. However, since most of the studies remain on a theoretical, cognitive level in their method of inquiry and resolution, it seems appropriate to ask: How far have we come to understand and assist students in the problems they face when *really conducting* an experiment? In our view, this implies not only their acquisition of a theoretical concept but also their understanding of the role of uncertainty in scientific measurement and experimental inquiry in the *process of real experimental handling*.

To assess this reasoning *in action* rather than the reasoning *on action*, 32 students were surveyed in a triangulation study. They were first asked to fill out an online survey about a simple experimental task, EXP1. Subsequently, they were observed by video recording conducting an experiment, EXP2, which was very similar to EXP1, in the laboratory. After the survey and the laboratory task, they were interviewed on their reasoning using the video recordings. We found that reasoning in the survey deviated considerably from that in the laboratory task. An important factor of the students' difficulties in the second task was due to missing connections between the different aspects of experimental research. These results, which are part of a larger study on students' reasoning, of the analysis of the corresponding instructive literature and of the historical evolution of the mathematical methods concerned, influenced the design of a *model of action-guiding cognitions*.

Keywords: measurement, measurement uncertainty, measurement error, experiment, students' understanding of measurement

BACKGROUND, RATIONALE, FRAMEWORK, AND PURPOSE

Studies of Seré and Larcher (1993), Lubben and Millar (1996), Buffler *et al.* (2001), Volkwyn *et al.* (2008), and others, have brought valuable insight into students' understanding of measurement, especially where the handling of data and calculation of uncertainty are concerned. However, all these studies employed written surveys to assess the students' notions when discussing a specific (theoretical) action taken in the laboratory. Consequently, we have to raise the question whether these cognitive aspects alone can offer an extensive exploration of the problem. Maisch (2010), for example, indicated that students performed very differently depending on whether they where asked to conduct, design or solely execute an experimental task in the laboratory. It seems therefore reasonable to assume that the differences might be even more apparent when comparing the reasoning given *on* a theoretical laboratory situation to those that are given and become effective *in the conduction* of a real laboratory task. (Within the social sciences, the gap between the two concerning everyday life situations has brought forth a whole new branch of research.)

The leading research questions that can be deduced from this are therefore: What notions on the handling of data and their uncertainty can be observed in students' activities in the laboratory, and how do they correspond to their theoretical arguments on a similar situation? How can this reasoning be described in order to gain further insight into the students' notions and learning difficulties? What information can be drawn from this to influence the design of a laboratory that includes adequate teaching methods about the nature and the handling of measurement data and uncertainty?

METHODS

In a qualitative study, 32 physics students were surveyed in a three-step methodological design. All students were in their third year of study and thus had concluded one year of intensive laboratory introduction in different fields of physics. As in prior studies, and based on the instrument developed and described by Buffler *et al.* (2001), the students were first asked to fill in an (online) questionnaire on a mechanical experiment. The questionnaire guided them through different questions and situations requiring decisions in the evolution of a fictional experimental process. We used the same context as Buffler *et al.* (2001), in which a ball rolls down a (fixed) slope and hits the ground after travelling some distance d, leaving an imprint on the floor. The length of the trajectory here obviously depends on the height h of the starting point on the slope. All items of the questionnaire (e.g. for the requirement of another reading, the choice of the result of a measurement series or the comparison between different data and data sets) required an assessment of the presented data and especially their uncertainty.

After finding the results of the survey in good agreement with prior studies (e.g. Buffler *et al.* 2009), we extended the investigation to a practical task. In this second step of the triangulation study, the students were asked to conduct a very similar experiment in a practical laboratory task. The major difference between the two was that the variable parameter was not the height of the effective slope, but its shape that could be formed to different shapes of a curvature. The students conducted the experiment in small groups of two or three. The actions of the students were videotaped but not closely observed by another person in order to establish a situation as similar to the typical first year laboratory as possible.

Following the practical laboratory task, the student groups were questioned on their approach to and proceedings during the task. Clips from the tape recordings were shown during the discussions for mnemonic and transparency reasons. All questionnaires, videos and interviews were evaluated using a content analysis approach, while the latter were also supported by hermeneutic methods in the richer parts of the discussions.

RESULTS

The results of the studies provided a more precise description and understanding of the students' reasoning on action, as well as valuable insight into the difference between their reasoning on action and reasoning in action as well as the reasons for this divergence.

Description of the students' notions by means of the Model of action-guiding cognitions
